

Introduction

Double data rate (DDR) transmission is used in many applications where fast data transmission is needed, such as memory access and first-in first-out (FIFO) memory structures. DDR uses both edges of a clock to transmit data, which facilitates data transmission at twice the rate of a single data rate (SDR) architecture using the same clock speed. This method also reduces the number of I/O pins required to transmit data.

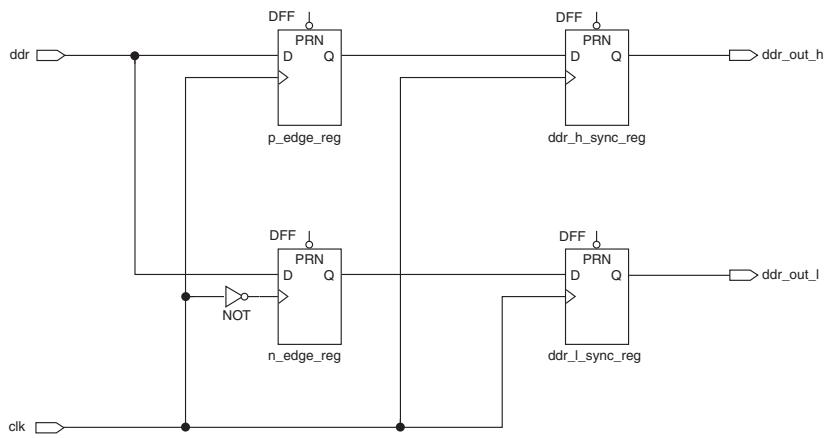

This chapter shows implementations of a double data rate I/O interface using Cyclone® devices. Cyclone devices support DDR input, DDR output, and bidirectional DDR signaling.

For more information on using Cyclone devices in applications with DDR SDRAM and FCRAM memory devices, refer to “[DDR Memory Support](#)” on page 10–4.

Double Data Rate Input

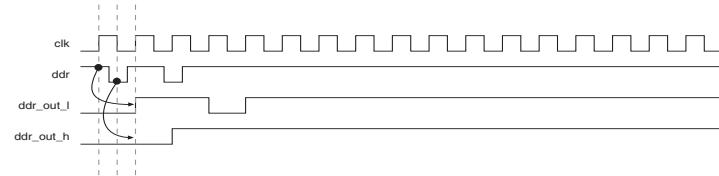

The DDR input implementation shown in [Figure 10–1](#) uses four internal logic element (LE) registers located in the logic array block (LAB) adjacent to the DDR input pin. The DDR data is fed to the first two of four registers. One register captures the DDR data present during the rising edge of the clock. The second register captures the DDR data present during the falling edge of the clock.

Figure 10–1. Double Data Rate Input Implementation

The third and fourth registers synchronize the two data streams to the rising edge of the clock. [Figure 10-2](#) shows examples of functional waveforms from a double data rate input implementation.

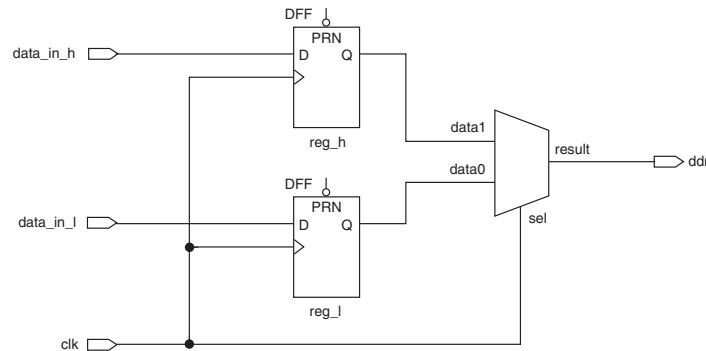

Figure 10-2. Double Data Rate Input Functional Waveforms

Double Data Rate Output

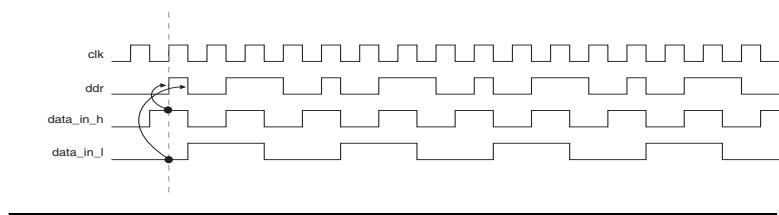

[Figure 10-3](#) shows a schematic representation of double data rate output implemented in a Cyclone device. The DDR output logic is implemented using LEs in the LAB adjacent to the output pin. Two registers are used to synchronize two serial data streams. The registered outputs are then multiplexed by the common clock to drive the DDR output pin at two times the data rate.

Figure 10-3. Double Data Rate Output Implementation

While the clock signal is logic-high, the output from `reg_h` is driven onto the DDR output pin. While the clock signal is logic-low, the output from `reg_l` is driven onto the DDR output pin. The DDR output pin can be any available user I/O pin.

[Figure 10-4](#) shows examples of functional waveforms from a double data rate output implementation.

Figure 10–4. Double Data Rate Output Waveforms

Bidirectional Double Data Rate

Figure 10–5 shows a bidirectional DDR interface, constructed using the DDR input and DDR output examples described in the previous two sections. As with the DDR input and DDR output examples, the bidirectional DDR pin can be any available user I/O pin, and the registers used to implement DDR bidirectional logic are LEs in the LAB adjacent to that pin. The tri-state buffer (TRI) controls when the device drives data onto the bidirectional DDR pin.

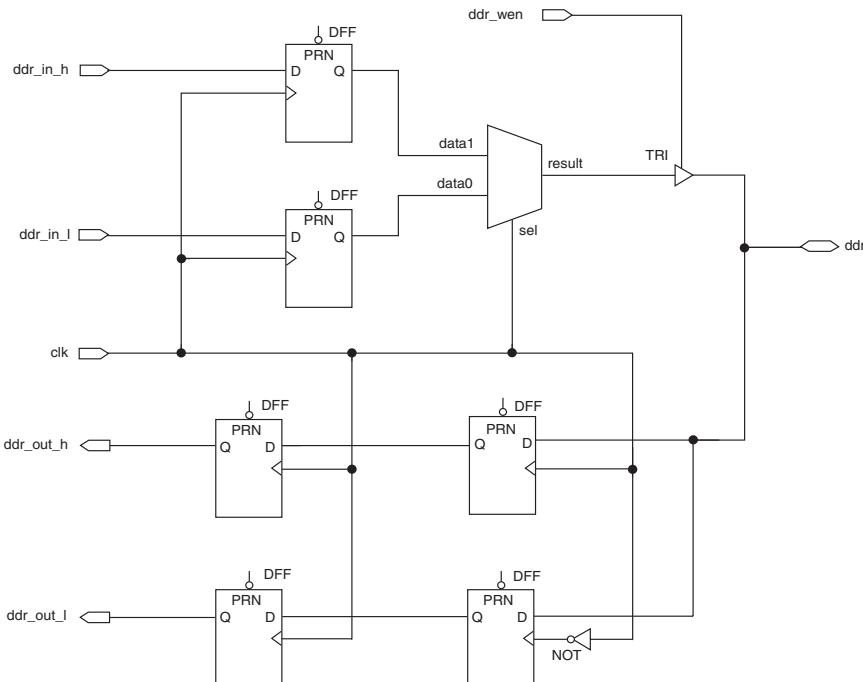

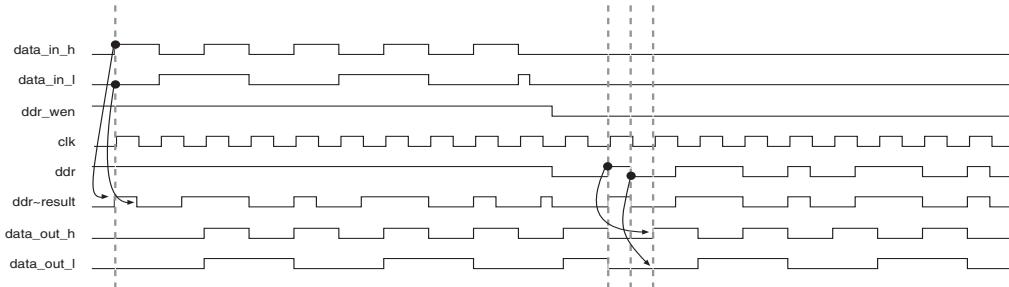

Figure 10–5. Bidirectional Double Data Rate Implementation

Figure 10–6 shows example waveforms from a bidirectional double data rate implementation.

DDR Memory Support

The Cyclone device family supports both DDR SDRAM and FCRAM memory interfaces up to 133 MHz.

For more information about extended DDR memory support in Cyclone devices, refer to the *Cyclone FPGA Family Data Sheet* section of the *Cyclone Device Handbook*.

Conclusion

Utilizing both the rising and falling edges of a clock signal, double data rate transmission is a popular strategy for increasing the speed of data transmission while reducing the required number of I/O pins. Cyclone devices can be used to implement this strategy for use in applications such as FIFO structures, SDRAM/FCRAM interfaces, as well as other time-sensitive memory access and data-transmission situations.

Document Revision History

Table 10–1 shows the revision history for this chapter.

Table 10–1. Document Revision History		
Date and Document Version	Changes Made	Summary of Changes
May 2008 v1.2	Minor textual and style changes. Added “Referenced Documents” section.	—
January 2007 v1.1	Added document revision history.	—
May 2003 v1.0	Added document to Cyclone Device Handbook.	—
