Revision History

1.0 Introduction

These processors are a 64-bit, multi-core processors built on 10-nanometer process technology.

Intel [®] Core[™] Processors includes the Intel [®] Performance Hybrid architecture, P-Cores for performance and E-Cores for Efficiency. Refer to [Table 1 o](#page-14-0)n page 15 for availability in Intel processor lines. For more details on P-Core and E-Core, refer to [Power and Performance Technologies](#page-43-0) on page 44.

The S-Processor Line offered in a 2-Chip Platform that includes the Processor Die and Platform Controller Hub (PCH-S) die in LGA and BGA Package.

The S Refresh-Processor Line offered in a 2-Chip Platform that includes the Processor Die and Platform Controller Hub (PCH-S) die in LGA Package.

S Processor line naming conventions in this document:

- S Processor when referring to S LGA Processor Line.
- S LGA when referring to S LGA Processor line.
- HX when referring S BGA Processor Line.

S-Refresh Processor line naming conventions in this document:

- S-Refresh Processor when referring to S Refresh LGA Processor Line.
- S-Refresh LGA when referring to S Refresh LGA Processor line.
- HX-Refresh when referring S Refresh BGA Processor Line.

The P/H/U-Processor Line offered in a 2 Die Multi Chip Package (MCP) that includes the Processor Die and Platform Controller Hub (PCH-P) die on the same package as the processor die.

The H Refresh-Processor Line offered in a 2 Die Multi Chip Package (MCP) that includes the Processor Die and Platform Controller Hub (PCH-P) die on the same package as the processor die.

The U Refresh-Processor Line offered in a 2 Die Multi Chip Package (MCP) that includes the Processor Die and Platform Controller Hub (PCH-P) die on the same package as the processor die.

The PX-Processor Line offered in a 2 Die Multi Chip Package (MCP) that includes the Processor Die and Platform Controller Hub (PCH-PX) die on the same package as the processor die. The PX has smaller package size compared to the P package.

The E/E Refresh-Processor Line offered in a 2-Chip Platform that includes the Processor Die and Platform Controller Hub (PCH-S) die in LGA Package.

The following table describes the different processor lines:

Processor Volatility Statement 1.1

The processor families do not retain any end-user data when powered down and/or when the processor is physically removed.

NOTE

Powered down refers to the state which all processor power rails are off.

Package Support 1.2

The S/S Refresh Processor lines are available in the following package:

- LGA1700
	- $-$ A 45 X 37.5 mm
	- $-$ Substrate Z=1.116 mm +/-0.95
	- $-$ Substrate + Die Z is $1.116+0.37=$ 1.486 mm

The E-Processor line is available in the following packages:

- LGA1700
	- $-$ A 45 X 37.5 mm
	- $-$ Substrate Z=1.116 mm +/-0.95
	- $-$ Substrate + Die Z is $1.116+0.37=$ 1.486 mm

The HX/HX Refresh-Processor line is available in the following packages:

- BGA1964
	- $-$ A 45 X 37.5 mm
	- $-$ Substrate Z = 0.594+/-0.08 mm
	- 1.185±0.096 (BOTTOM OF BGA TO TOP OF DIE)

The P/H/U/U Refresh/H Refresh-Processor line is available in the following packages:

- BGA1744
	- $-$ A 25 X 50 mm
	- $-$ Substrate Z = 0.594+/-0.08 mm
	- 1.185±0.096 (BOTTOM OF BGA TO TOP OF DIE)

The PX-Processor line is available in the following packages:

- BGA1792
	- $-$ A 25 X 40 mm
	- $-$ Substrate Z = 0.594+/-0.08 mm
	- $-$ 1.171 \pm 0.082 (BOTTOM OF BGA TO TOP OF DIE)

Supported Technologies 1.3

• PECI – Platform Environmental Control Interface

- Intel[®] Virtualization Technology (Intel[®] VT-x)
- Intel[®] Virtualization Technology for Directed I/O (Intel[®] VT-d)
- Intel® APIC Virtualization Technology (Intel® APICv)
- Hypervisor-Managed Linear Address Translation (HLAT)
- Intel® Trusted Execution Technology (Intel ®TXT)
- Intel[®] Advanced Encryption Standard New Instructions (Intel[®] AES-NI)
- PCLMULQDQ (Perform Carry-Less Multiplication Quad word) Instruction
- Intel® Secure Key
- Execute Disable Bit
- Intel[®] Boot Guard
- SMEP Supervisor Mode Execution Protection
- SMAP Supervisor Mode Access Protection
- SHA Extensions Secure Hash Algorithm Extensions
- UMIP User Mode Instruction Prevention
- RDPID Read Processor ID
- Intel[®] Total Memory Encryption (Intel[®] TME)
- Intel[®] Control-flow Enforcement Technology (Intel[®] CET)
- KeyLocker Technology
- Devils gate Rock (DGR)
- Smart Cache Technology
- IA Core Level 1 and Level 2 Caches
- Intel's Performance Hybrid Architecture
- Intel ® Turbo Boost Technology 2.0
- Intel® Turbo Boost Max Technology 3.0
- PAIR Power Aware Interrupt Routing
- Intel® Hyper-Threading Technology (Intel® HT Technology)
- Intel SpeedStep® Technology
- Intel® Speed Shift Technology
- Intel® Advanced Vector Extensions 2 (Intel® AVX2)
- Intel® AVX2 Vector Neural Network Instructions (Intel® AVX2 VNNI)
- Intel® 64 Architecture x2APIC
- Intel[®] Dynamic Tuning technology (Intel[®] DTT)
- Intel® GNA 3.0 (GMM and Neural Network Accelerator)
- Intel[®] Image Processing Unit (Intel[®] IPU)
- Cache Line Write Back (CLWB)
- Intel[®] Processor Trace
- Platform CrashLog
- Telemetry Aggregator

• Integrated Reference Clock PLL

NOTE

The availability of the features above may vary between different processor SKUs. Refer to [Technologies](#page-28-0) on page 29 for more information.

API Support (Windows*) 1.3.1

- Direct3D* 2015, Direct3D 12, Direct3D 11.2, Direct3D 11.1, Direct3D 9, Direct3D 10, Direct2D
- OpenGL* 4.5
- Open CL* 2.1, Open CL* 2.0, Open CL* 1.2, Open CL* 3.0

DirectX* extensions:

• PixelSync, Instant Access, Conservative Rasterization, Render Target Reads, Floating-point De-norms, Shared a Virtual memory, Floating Point atomics, MSAA sample-indexing, Fast Sampling (Coarse LOD), Quilted Textures, GPU Enqueue Kernels, GPU Signals processing unit. Other enhancements include color compression.

Gen 13 architecture delivers hardware acceleration of Direct X^* 12 Render pipeline comprising of the following stages: Vertex Fetch, Vertex Shader, Hull Shader, Tessellation, Domain Shader, Geometry Shader, Rasterizer, Pixel Shader, Pixel Output.

Power Management Support 1.4

Processor Core Power Management 1.4.1

- Full support of ACPI C-states as implemented by the following processor C-states: — C0, C1, C1E, C6, C8, C10
- Enhanced Intel SpeedStep® Technology
- Intel ® Speed Shift Technology

Refer to [Processor IA Core Power Management](#page-63-0) on page 64 for more information.

System Power Management 1.4.2

Refer to [Power Management](#page-61-0) on page 62 for more information.

Memory Controller Power Management 1.4.3

- Disabling Unused System Memory Outputs
- DRAM Power Management and Initialization
- Initialization Role of CKE
- Conditional Self-Refresh
- Dynamic Power Down
- DRAM I/O Power Management
- DDR Electrical Power Gating (EPG)
- Power Training

Refer to [Integrated Memory Controller \(IMC\) Power Management](#page-128-0) on page 129 for more information

Processor Graphics Power Management 1.4.4

Memory Power Savings Technologies

- Intel[®] Rapid Memory Power Management (Intel[®] RMPM)
- Intel[®] Smart 2D Display Technology (Intel[®] S2DDT)

Display Power Savings Technologies

- Intel[®] (Seamless and Static) Display Refresh Rate Switching (DRRS) with eDP^{*} port
- Intel [®] OLED Power Saving Technology (Intel [®] OPST) 1.1
- Intel[®] Display Power Saving Technology (Intel[®] DPST 7.1)
- Panel Self-Refresh 2 (PSR 2)
- Low-Power Single Pipe (LPSP)
- Low-Power Dual Pipe (LPDP)

Graphics Core Power Savings Technologies

- Graphics Dynamic Frequency
- Intel[®] Graphics Render Standby Technology (Intel[®] GRST)
- Intel Capped Frames Per Second (CFPS)

Thermal Management Support 1.5

- Digital Thermal Sensor
- Intel® Adaptive Thermal Monitor
- THERMTRIP# and PROCHOT# support
- On-Demand Mode
- Memory Thermal Throttling
- External Thermal Sensor (TS-on-DIMM and TS-on-Board)

- Render Thermal Throttling
- Fan Speed Control with DTS
- Intel® Turbo Boost Technology 2.0 Power Control
- Intel[®] Dynamic Tuning technology (Intel[®] DTT)

Refer to [Thermal Management](#page-75-0) on page 76 for more information.

Ball-out Information 1.6

For information on the ballout of S/S Refresh/E download the pdf, click \emptyset on the navigation pane and refer the spreadsheet, **743844-001_S_LGA_Ballout.xlsx**.

For information on H, P, U, U Refresh and H Refresh processors ball information, download the pdf, click \oslash on the navigation pane and refer the spreadsheet, **743844-001_HPU_Ballout.xlsx**.

For information on PX processor ball information, download the pdf, click $\mathcal O$ on the navigation pane and refer the spreadsheet, **743844-001_PX_Ballout.xlsm**.

For information on HX processor ball information, download the pdf, click $\mathcal O$ on the navigation pane and refer the spreadsheet, **743844-001_HX_Ballout.xlsx**.

Processor Testability 1.7

A DCI on-board connector should be placed, to enable 13th Generation Intel $^{\circledast}$ Core^r^{*} and Intel ® 14 th Generation full debug capabilities.

For 13th Generation Intel ® Core™ and Intel ® 14th Generation processor lines, a Direct Connect Interface Tool connector is highly recommended to enable lower C-state to debug.

The processor includes boundary-scan for board and system level testability.

Operating Systems Support 1.8

Related Documents 1.10

2.0 Technologies

This chapter provides a high-level description of Intel technologies implemented in the processor.

The implementation of the features may vary between the processor SKUs.

Details on the different technologies of Intel processors and other relevant external notes are located at the Intel technology web site: <http://www.intel.com/technology/>

NOTE

The last section of this chapter is dedicated to deprecated technologies. These technologies are not supported in this processor but were supported in previous generations.

Platform Environmental Control Interface 2.1

Platform Environmental Control Interface (PECI) is an Intel proprietary interface that provides a communication channel between Intel processors and external components such as Super IO (SIO) and Embedded Controllers (EC) to provide processor temperature, Turbo, Assured Power (cTDP), and Memory Throttling Control mechanisms and many other services. PECI is used for platform thermal management and real-time control and configuration of processor features and performance.

NOTE

• PECI over eSPI is supported.

PECI Bus Architecture 2.1.1

The PECI architecture is based on a wired-OR bus that the clients (as processor PECI) can pull up (with the strong drive).

The idle state on the bus is '0' (logical low) and near zero (Logical voltage level).

NOTE

PECI supported frequency range is 3.2 kHz - 1 MHz.

The following figures demonstrate PECI design and connectivity:

- PECI Host-Clients Connection: While the host/originator can be third party PECI host and one of the PECI client is a processor PECI device.
- PECI EC Connection.

^R *Intel® Core™ and Xeon™ E 2400 Processors—Technologies*

Figure 8. Example for PECI Host-Clients Connection

Figure 9. Example for PECI EC Connection

Intel® Virtualization Technology 2.2

Intel® Virtualization Technology (Intel® VT) makes a single system appear as multiple independent systems to software. This allows multiple, independent operating systems to run simultaneously on a single system. Intel[®] VT comprises technology components to support Virtualization of platforms based on Intel® architecture microprocessors and chipsets.

Intel® Virtualization Technology (Intel® VT) Intel® 64 and Intel® Architecture (Intel® VT-x) added hardware support in the processor to improve the Virtualization performance and robustness. Intel® Virtualization Technology for Directed I/O (Intel® VT-d) extends Intel[®] VT-x by adding hardware assisted support to improve I/O device Virtualization performance.

Intel® VT-x specifications and functional descriptions are included in the *Intel*® *64 Architectures Software Developer's Manual, Volume 3*. Available at:

<http://www.intel.com/products/processor/manuals>

The Intel[®] VT-d specification and other VT documents can be referenced at:

[http://www.intel.com/content/www/us/en/virtualization/virtualization-technology/](http://www.intel.com/content/www/us/en/virtualization/virtualization-technology/intel-virtualization-technology.html).

Intel® VT for Intel® 64 and Intel® Architecture 2.2.1

Objectives

Intel® Virtualization Technology for Intel® 64 and Intel® Architecture (Intel® VT-x) provides hardware acceleration for virtualization of IA platforms. Virtual Machine Monitor (VMM) can use Intel® VT-x features to provide an improved reliable Virtualization platform. By using Intel® VT-x, a VMM is:

- **Robust:** VMMs no longer need to use para-virtualization or binary translation. This means that VMMs will be able to run off-the-shelf operating systems and applications without any special steps.
- **Enhanced:** Intel® VT enables VMMs to run 64-bit guest operating systems on IA x86 processors.
- **More Reliable:** Due to the hardware support, VMMs can now be smaller, less complex, and more efficient. This improves reliability and availability and reduces the potential for software conflicts.
- **More Secure:** The use of hardware transitions in the VMM strengthens the isolation of VMs and further prevents corruption of one VM from affecting others on the same system.

Key Features

The processor supports the following added new Intel $^{\circ}$ VT-x features:

- **Mode-based Execute Control for EPT (MBEC)** A mode of EPT operation which enables different controls for executability of Guest Physical Address (GPA) based on Guest specified mode (User/ Supervisor) of linear address translating to the GPA. When the mode is enabled, the executability of a GPA is defined by two bits in EPT entry. One bit for accesses to user pages and other one for accesses to supervisor pages.
	- This mode requires changes in VMCS and EPT entries. VMCS includes a bit "Mode-based execute control for EPT" which is used to enable/disable the mode. An additional bit in EPT entry is defined as "execute access for usermode linear addresses"; the original EPT execute access bit is considered as "execute access for supervisor-mode linear addresses". If the "mode-based execute control for EPT" VM-execution control is disabled the additional bit is ignored and the system work with one bit i.e. the original bit, for execute control for both user and supervisor pages.
	- Behavioral changes Behavioral changes are across three areas:
		- **Access to GPA -** If the "Mode-based execute control for EPT" VMexecution control is 1, treatment of guest-physical accesses by instruction fetches depends on the linear address from which an instruction is being fetched.
			- 1. If the translation of the linear address specifies user mode (the U/S bit was set in every paging structure entry used to translate the linear address), the resulting guest-physical address is executable under EPT only if the XU bit (at position 10) is set in every EPT paging-structure entry used to translate the guest-physical address.

- 2. If the translation of the linear address specifies supervisor mode (the U/ S bit was clear in at least one of the paging-structure entries used to translate the linear address), the resulting guest-physical address is executable under EPT only if the XS bit is set in every EPT pagingstructure entry used to translate the guest-physical address.
- The XU and XS bits are used only when translating linear addresses for guest code fetches. They do not apply to guest page walks, data accesses, or A/D-bit updates.
- **VMEntry -** If the **"**activate secondary controls" and "Mode-based execute control for EPT" VM-execution controls are both 1, VM entries ensure that the "enable EPT" VM-execution control is 1. VM entry fails if this check fails. When such a failure occurs, control is passed to the next instruction.
- **VMExit** The exit qualification due to EPT violation reports clearly whether the violation was due to User mode access or supervisor mode access.
	- Capability Querying: IA32_VMX_PROCBASED_CTLS2 has bit to indicate the capability, RDMSR can be used to read and query whether the processor supports the capability or not.
- Extended Page Table (EPT) Accessed and Dirty Bits
	- EPT A/D bits enabled VMMs to efficiently implement memory management and page classification algorithms to optimize VM memory operations, such as defragmentation, paging, live migration, and check-pointing. Without hardware support for EPT A/D bits, VMMs may need to emulate A/D bits by marking EPT paging-structures as not-present or read-only, and incur the overhead of EPT page-fault VM exits and associated software processing.
- EPTP (EPT pointer) switching
	- EPTP switching is a specific VM function. EPTP switching allows guest software (in VMX non-root operation, supported by EPT) to request a different EPT paging-structure hierarchy. This is a feature by which software in VMX nonroot operation can request a change of EPTP without a VM exit. The software will be able to choose among a set of potential EPTP values determined in advance by software in VMX root operation.
- Pause loop exiting
	- Support VMM schedulers seeking to determine when a virtual processor of a multiprocessor virtual machine is not performing useful work. This situation may occur when not all virtual processors of the virtual machine are currently scheduled and when the virtual processor in question is in a loop involving the PAUSE instruction. The new feature allows detection of such loops and is thus called PAUSE-loop exiting.

The processor IA core supports the following Intel® VT-x features:

- Extended Page Tables (EPT)
	- EPT is hardware assisted page table virtualization
	- It eliminates VM exits from guest OS to the VMM for shadow page-table maintenance
- Virtual Processor IDs (VPID)
	- Ability to assign a VM ID to tag processor IA core hardware structures (such as TLBs)

- This avoids flushes on VM transitions to give a lower-cost VM transition time and an overall reduction in virtualization overhead.
- Guest Preemption Timer
	- The mechanism for a VMM to preempt the execution of a guest OS after an amount of time specified by the VMM. The VMM sets a timer value before entering a guest
	- The feature aids VMM developers in flexibility and Quality of Service (QoS) guarantees
- Descriptor-Table Exiting
	- Descriptor-table exiting allows a VMM to protect a guest OS from internal (malicious software based) attack by preventing the relocation of key system data structures like IDT (interrupt descriptor table), GDT (global descriptor table), LDT (local descriptor table), and TSS (task segment selector).
	- A VMM using this feature can intercept (by a VM exit) attempts to relocate these data structures and prevent them from being tampered by malicious software.

Intel® Virtualization Technology for Directed I/O 2.2.2

Intel® VT-d Objectives

The key Intel® Virtualization Technology (Intel® VT) for Directed I/O (Intel® VT-d) objectives are domain-based isolation and hardware-based virtualization. A domain can be abstractly defined as an isolated environment in a platform to which a subset of host physical memory is allocated. Intel® VT-d provides accelerated I/O performance for a Virtualization platform and provides software with the following capabilities:

- **I/O Device Assignment and Security**: for flexibly assigning I/O devices to VMs and extending the protection and isolation properties of VMs for I/O operations.
- **DMA Remapping**: for supporting independent address translations for Direct Memory Accesses (DMA) from devices.
- **Interrupt Remapping**: for supporting isolation and routing of interrupts from devices and external interrupt controllers to appropriate VMs.
- **Reliability**: for recording and reporting to system software DMA and interrupt errors that may otherwise corrupt memory or impact VM isolation.

Intel® VT-d accomplishes address translation by associating transaction from a given I/O device to a translation table associated with the Guest to which the device is assigned. It does this by means of the data structure in the following illustration. This table creates an association between the device's PCI Express* Bus/Device/Function (B/D/F) number and the base address of a translation table. This data structure is populated by a VMM to map devices to translation tables in accordance with the device assignment restrictions above and to include a multi-level translation table (VT-d Table) that contains Guest specific address translations.

Figure 10. Device to Domain Mapping Structures

Intel® VT-d functionality often referred to as an Intel® VT-d Engine, has typically been implemented at or near a PCI Express* host bridge component of a computer system. This might be in a chipset component or in the PCI Express functionality of a processor with integrated I/O. When one such VT-d engine receives a PCI Express transaction from a PCI Express bus, it uses the B/D/F number associated with the transaction to search for an Intel® VT-d translation table. In doing so, it uses the B/D/F number to traverse the data structure shown in the above figure. If it finds a valid Intel[®] VT-d table in this data structure, it uses that table to translate the address provided on the PCI Express bus. If it does not find a valid translation table for a given translation, this results in an Intel® VT-d fault. If Intel® VT-d translation is required, the Intel® VT-d engine performs an N-level table walk.

intel

For more information, refer to *Intel*® *Virtualization Technology for Directed I/O Architecture Specification* [http://www.intel.com/content/dam/www/public/us/en/](http://www.intel.com/content/dam/www/public/us/en/documents/product-specifications/vt-directed-io-spec.pdf) [documents/product-specifications/vt-directed-io-spec.pdf](http://www.intel.com/content/dam/www/public/us/en/documents/product-specifications/vt-directed-io-spec.pdf)

Intel® VT-d Key Features

The processor supports the following Intel® VT-d features:

- Memory controller and processor graphics comply with the Intel[®] VT-d 2.1 Specification.
- Two Intel[®] VT-d DMA remap engines.
	- iGFX DMA remap engine
	- Default DMA remap engine (covers all devices except iGFX)
- Support for root entry, context entry, and the default context
- 46-bit guest physical address and host physical address widths
- Support for 4K page sizes only
- Support for register-based fault recording only (for single entry only) and support for MSI interrupts for faults
- Support for both leaf and non-leaf caching
- Support for boot protection of default page table
- Support for non-caching of invalid page table entries
- Support for hardware-based flushing of translated but pending writes and pending reads, on IOTLB invalidation
- Support for Global, Domain-specific and Page specific IOTLB invalidation
- MSI cycles (MemWr to address FEEx_xxxxh) not translated.
- Interrupt Remapping is supported
- Queued invalidation is supported
- Intel[®] VT-d translation bypass address range is supported (Pass Through)

The processor supports the following added new Intel® VT-d features:

- 4-level Intel[®] VT-d Page walk both default Intel[®] VT-d engine, as well as the Processor Graphics VT-d engine are upgraded to support 4-level Intel® VT-d tables (adjusted guest address width of 48 bits)
- Intel[®] VT-d super-page support of Intel[®] VT-d super-page (2 MB, 1 GB) for default Intel® VT-d engine (that covers all devices except IGD)

IGD Intel® VT-d engine does not support super-page and BIOS should disable super-page in default Intel[®] VT-d engine when iGfx is enabled.

NOTE

Intel® VT-d Technology may not be available on all SKUs.

Intel® APIC Virtualization Technology (Intel® APICv) 2.2.3

APIC virtualization is a collection of features that can be used to support the virtualization of interrupts and the Advanced Programmable Interrupt Controller (APIC).

When APIC virtualization is enabled, the processor emulates many accesses to the APIC, tracks the state of the virtual APIC, and delivers virtual interrupts — all in VMX non-root operation without a VM exit.

The following are the VM-execution controls relevant to APIC virtualization and virtual interrupts:

- **Virtual-interrupt Delivery.** This controls enables the evaluation and delivery of pending virtual interrupts. It also enables the emulation of writes (memorymapped or MSR-based, as enabled) to the APIC registers that control interrupt prioritization.
- **Use TPR Shadow.** This control enables emulation of accesses to the APIC's taskpriority register (TPR) via CR8 and, if enabled, via the memory-mapped or MSRbased interfaces.
- **Virtualize APIC Accesses.** This control enables virtualization of memory-mapped accesses to the APIC by causing VM exits on accesses to a VMM-specified APICaccess page. Some of the other controls, if set, may cause some of these accesses to be emulated rather than causing VM exits.
- **Virtualize x2APIC Mode.** This control enables virtualization of MSR-based accesses to the APIC.
- **APIC-register Virtualization.** This control allows memory-mapped and MSRbased reads of most APIC registers (as enabled) by satisfying them from the virtual-APIC page. It directs memory-mapped writes to the APIC-access page to the virtual-APIC page, following them by VM exits for VMM emulation.
- **Process Posted Interrupts.** This control allows software to post virtual interrupts in a data structure and send a notification to another logical processor; upon receipt of the notification, the target processor will process the posted interrupts by copying them into the virtual-APIC page.

NOTE

Intel® APIC Virtualization Technology may not be available on all SKUs.

Intel® APIC Virtualization specifications and functional descriptions are included in the *Intel*® *64 Architectures Software Developer's Manual, Volume 3*. Available at:

<http://www.intel.com/products/processor/manuals>

Hypervisor-Managed Linear Address Translation 2.2.4

Hypervisor-Managed Linear Address Translation (HLAT) is active when the "enable HLAT" VM-execution control is 1. The processor looks up the HLAT if, during a guest linear address translation, the guest linear address matches the Protected Linear Range. The lookup from guest linear addresses to the guest physical address and attributes is determined by a set of HLAT paging structures.

The guest paging structure managed by the guest OS specifies the ordinary translation of a guest linear address to the guest physical address and attributes that the guest ring-0 software has programmed, whereas HLAT specifies the alternate translation of the guest linear address to guest physical address and attributes that the Secure Kernel and VMM seek to enforce. A logical processor uses HLAT to translate guest linear addresses only when those guest linear addresses are used to access memory (both for code fetch and data load/store) and the guest linear addresses match the PLR programmed by the VMM/Secure Kernel.

HLAT specifications and functional descriptions are included in the Intel® Architecture Instruction Set Extensions Programming Reference. Available at:

[https://software.intel.com/en-us/download/intel-architecture-instruction-set](https://software.intel.com/en-us/download/intel-architecture-instruction-set-extensions-programming-reference)[extensions-programming-reference](https://software.intel.com/en-us/download/intel-architecture-instruction-set-extensions-programming-reference)

Security Technologies 2.3

Intel® Trusted Execution Technology 2.3.1

Intel® Trusted Execution Technology (Intel® TXT) defines platform-level enhancements that provide the building blocks for creating trusted platforms.

The Intel® TXT platform helps to provide the authenticity of the controlling environment such that those wishing to rely on the platform can make an appropriate trust decision. The Intel® TXT platform determines the identity of the controlling environment by accurately measuring and verifying the controlling software.

Another aspect of the trust decision is the ability of the platform to resist attempts to change the controlling environment. The Intel[®] TXT platform will resist attempts by software processes to change the controlling environment or bypass the bounds set by the controlling environment.

Intel® TXT is a set of extensions designed to provide a measured and controlled launch of system software that will then establish a protected environment for itself and any additional software that it may execute.

These extensions enhance two areas:

- The launching of the Measured Launched Environment (MLE).
- The protection of the MLE from potential corruption.

The enhanced platform provides these launch and control interfaces using Safer Mode Extensions (SMX).

The SMX interface includes the following functions:

- Measured/Verified launch of the MLE.
- Mechanisms to ensure the above measurement is protected and stored in a secure location.
- Protection mechanisms that allow the MLE to control attempts to modify itself.

The processor also offers additional enhancements to System Management Mode (SMM) architecture for enhanced security and performance. The processor provides new MSRs to:

• Enable a second SMM range

- Enable SMM code execution range checking
- Select whether SMM Save State is to be written to legacy SMRAM or to MSRs
- Determine if a thread is going to be delayed entering SMM
- Determine if a thread is blocked from entering SMM
- Targeted SMI, enable/disable threads from responding to SMIs, both VLWs, and IPI

For the above features, BIOS should test the associated capability bit before attempting to access any of the above registers. The capability bits are discussed in the register description.

For more information, refer to the Intel® Trusted Execution Technology Measured Launched Environment Programming Guide at:

[http://www.intel.com/content/www/us/en/software-developers/intel-txt-software](http://www.intel.com/content/www/us/en/software-developers/intel-txt-software-development-guide.html)[development-guide.html.](http://www.intel.com/content/www/us/en/software-developers/intel-txt-software-development-guide.html)

NOTE

Intel® TXT Technology may not be available on all SKUs.

Intel® Advanced Encryption Standard New Instructions 2.3.2

The processor supports Intel[®] Advanced Encryption Standard New Instructions (Intel[®] AES-NI) that are a set of Single Instruction Multiple Data (SIMD) instructions that enable fast and secure data encryption and decryption based on the Advanced Encryption Standard (AES). Intel® AES-NI is valuable for a wide range of cryptographic applications, such as applications that perform bulk encryption/ decryption, authentication, random number generation, and authenticated encryption. AES is broadly accepted as the standard for both government and industrial applications and is widely deployed in various protocols.

Intel® AES-NI consists of six Intel® SSE instructions. Four instructions, AESENC, AESENCLAST, AESDEC, and AESDELAST facilitate high-performance AES encryption and decryption. The other two, AESIMC and AESKEYGENASSIST, support the AES key expansion procedure. Together, these instructions provide full hardware for supporting AES; offering security, high performance, and a great deal of flexibility.

This generation of the processor has increased the performance of the Intel® AES-NI significantly compared to previous products.

The Intel® AES-NI specifications and functional descriptions are included in the *Intel*® *64 Architectures Software Developer's Manual, Volume 2*. Available at:

<http://www.intel.com/products/processor/manuals>

NOTE

Intel® AES-NI Technology may not be available on all SKUs.

intel

Perform Carry-Less Multiplication Quad Word Instruction 2.3.3

The processor supports the carry-less multiplication instruction, ie, Perform Carry-Less Multiplication Quad Word Instruction (PCLMULQDQ). PCLMULQDQ is a Single Instruction Multiple Data (SIMD) instruction that computes the 128-bit carry-less multiplication of two 64-bit operands without generating and propagating carries. Carry-less multiplication is an essential processing component of several cryptographic systems and standards. Hence, accelerating carry-less multiplication can significantly contribute to achieving high-speed secure computing and communication.

PCLMULQDQ specifications and functional descriptions are included in the *Intel*® *64 Architectures Software Developer's Manual, Volume 2*. Available at:

<http://www.intel.com/products/processor/manuals>

Intel® Secure Key 2.3.4

The processor supports Intel® Secure Key (formerly known as Digital Random Number Generator or DRNG), a software visible random number generation mechanism supported by a high-quality entropy source. This capability is available to programmers through the RDRAND instruction. The resultant random number generation capability is designed to comply with existing industry standards in this regard (ANSI X9.82 and NIST SP 800-90).

Some possible usages of the RDRAND instruction include cryptographic key generation as used in a variety of applications, including communication, digital signatures, secure storage, etc.

RDRAND specifications and functional descriptions are included in the *Intel*® *64 Architectures Software Developer's Manual, Volume 2*. Available at:

<http://www.intel.com/products/processor/manuals>

Execute Disable Bit 2.3.5

The Execute Disable Bit allows memory to be marked as non-executable when combined with a supporting operating system. If code attempts to run in nonexecutable memory, the processor raises an error to the operating system. This feature can prevent some classes of viruses or worms that exploit buffer overrun vulnerabilities and can, thus, help improve the overall security of the system.

Boot Guard Technology 2.3.6

Boot Guard technology is a part of boot integrity protection technology. Boot Guard can help protect the platform boot integrity by preventing the execution of unauthorized boot blocks. With Boot Guard, platform manufacturers can create boot policies such that invocation of an unauthorized (or untrusted) boot block will trigger the platform protection per the manufacturer's defined policy.

With verification based in the hardware, Boot Guard extends the trust boundary of the platform boot process down to the hardware level.

Boot Guard accomplishes this by:

• Providing of hardware-based Static Root of Trust for Measurement (S-RTM) and the Root of Trust for Verification (RTV) using Intel architectural components.

- Providing of architectural definition for platform manufacturer Boot Policy.
- Enforcing manufacturer provided Boot Policy using Intel architectural components.

Benefits of this protection are that Boot Guard can help maintain platform integrity by preventing re-purposing of the manufacturer's hardware to run an unauthorized software stack.

NOTE

Boot Guard availability may vary between the different SKUs.

Intel® Supervisor Mode Execution Protection 2.3.7

Intel® Supervisor Mode Execution Protection (Intel® SMEP) is a mechanism that provides the next level of system protection by blocking malicious software attacks from user mode code when the system is running in the highest privilege level. This technology helps to protect from virus attacks and unwanted code from harming the system. For more information, refer to *Intel*® *64 Architectures Software Developer's Manual, Volume 3* at:

<http://www.intel.com/products/processor/manuals>

Intel® Supervisor Mode Access Protection 2.3.8

Intel® Supervisor Mode Access Protection (Intel® SMAP) is a mechanism that provides next level of system protection by blocking a malicious user from tricking the operating system into branching off user data. This technology shuts down very popular attack vectors against operating systems.

For more information, refer to the *Intel*® *64 Architectures Software Developer's Manual, Volume 3*:

<http://www.intel.com/products/processor/manuals>

Intel® Secure Hash Algorithm Extensions 2.3.9

The Intel® Secure Hash Algorithm Extensions (Intel® SHA Extensions) is one of the most commonly employed cryptographic algorithms. Primary usages of SHA include data integrity, message authentication, digital signatures, and data de-duplication. As the pervasive use of security solutions continues to grow, SHA can be seen in more applications now than ever. The Intel® SHA Extensions are designed to improve the performance of these compute-intensive algorithms on Intel® architecture-based processors.

The Intel[®] SHA Extensions are a family of seven instructions based on the Intel[®] Streaming SIMD Extensions (Intel® SSE) that are used together to accelerate the performance of processing SHA-1 and SHA-256 on Intel architecture-based processors. Given the growing importance of SHA in our everyday computing devices, the new instructions are designed to provide a needed boost of performance to hashing a single buffer of data. The performance benefits will not only help improve responsiveness and lower power consumption for a given application, but they may also enable developers to adopt SHA in new applications to protect data while delivering to their user experience goals. The instructions are defined in a way that simplifies their mapping into the algorithm processing flow of most software libraries, thus enabling easier development.

More information on Intel® SHA can be found at:

[http://software.intel.com/en-us/artTGLes/intel-sha-extensions](http://software.intel.com/en-us/articles/intel-sha-extensions)

User Mode Instruction Prevention 2.3.10

User Mode Instruction Prevention (UMIP) provides additional hardening capability to the OS kernel by allowing certain instructions to execute only in supervisor mode (Ring 0).

If the OS opt-in to use UMIP, the following instruction are enforced to run in supervisor mode:

- **SGDT** Store the GDTR register value
- **SIDT** Store the IDTR register value
- **SLDT** Store the LDTR register value
- **SMSW** Store Machine Status Word
- **STR** Store the TR register value

An attempt at such execution in user mode causes a general protection exception (#GP).

UMIP specifications and functional descriptions are included in the *Intel*® *64 Architectures Software Developer's Manual, Volume 3*. Available at:

<http://www.intel.com/products/processor/manuals>

Read Processor ID 2.3.11

A companion instruction that returns the current logical processor's ID and provides a faster alternative to using the RDTSCP instruction.

Read Processor ID (RDPID) specifications and functional descriptions are included in the *Intel*® *64 Architectures Software Developer's Manual, Volume 2*. Available at:

<http://www.intel.com/products/processor/manuals>

Intel® Total Memory Encryption - Multi-Key 2.3.12

This technology encrypts the platform's entire memory with multiple encryption keys. Intel[®] Total Memory Encryption (Intel[®] TME), when enabled via BIOS configuration, ensures that all memory accessed from the Intel processor is encrypted.

Intel TME encrypts memory accesses using the AES XTS algorithm with 128-bit keys. The global encryption key used for memory encryption is generated using a hardened random number generator in the processor and is not exposed to software.

Software (OS/VMM) manages the use of keys and can use each of the available keys for encrypting any page of the memory. Thus, Intel® Total Memory Encryption - Multikey (Intel® TME-MK) allows page granular encryption of memory. By default Intel TME-MK uses the Intel TME encryption key unless explicitly specified by software.

Data in-memory and on the external memory buses is encrypted and exists in plain text only inside the processor. This allows existing software to operate without any modification while protecting memory using Intel TME. Intel TME does not protect memory from modifications.

Intel TME allows the BIOS to specify a physical address range to remain unencrypted. Software running on Intel TME enabled system has full visibility into all portions of memory that are configured to be unencrypted by reading a configuration register in the processor.

NOTES

- Memory access to nonvolatile memory (Intel® Optane[™]) is encrypted as well.
- More information on Intel TME-MK can be found at:

[https://software.intel.com/sites/default/files/managed/a5/16/Total-Memory-](HTTPS://SOFTWARE.INTEL.COM/SITES/DEFAULT/FILES/MANAGED/A5/16/TOTAL-MEMORY-ENCRYPTION-MULTI-KEY-SPEC.PDF)[Encryption-Multi-Key-Spec.pdf](HTTPS://SOFTWARE.INTEL.COM/SITES/DEFAULT/FILES/MANAGED/A5/16/TOTAL-MEMORY-ENCRYPTION-MULTI-KEY-SPEC.PDF)

• A cold boot is required when enable/ disable Intel TME feature on this platform.

Intel® Control-flow Enforcement Technology 2.3.13

Return-oriented Programming (ROP), and similarly CALL/JMP-oriented programming (COP/JOP), have been the prevalent attack methodology for stealth exploit writers targeting vulnerabilities in programs.

Intel® Control-flow Enforcement Technology (Intel® CET) provides the following components to defend against ROP/JOP style control-flow subversion attacks:

Shadow Stack 2.3.13.1

A shadow stack is a second stack for the program that is used exclusively for control transfer operations. This stack is separate from the data stack and can be enabled for operation individually in user mode or supervisor mode.

The shadow stack is protected from tamper through the page table protections such that regular store instructions cannot modify the contents of the shadow stack. To provide this protection the page table protections are extended to support an additional attribute for pages to mark them as "Shadow Stack" pages. When shadow stacks are enabled, control transfer instructions/flows such as near call, far call, call to interrupt/exception handlers, etc. store their return addresses to the shadow stack. The RET instruction pops the return address from both stacks and compares them. If the return addresses from the two stacks do not match, the processor signals a control protection exception (#CP). Stores from instructions such as MOV, XSAVE, etc. are not allowed to the shadow stack.

Indirect Branch Tracking 2.3.13.2

The ENDBR32 and ENDBR64 (collectively ENDBRANCH) are two new instructions that are used to mark valid indirect CALL/JMP target locations in the program. This instruction is a NOP on legacy processors for backward compatibility.

The processor implements a state machine that tracks indirect JMP and CALL instructions. When one of these instructions is seen, the state machine moves from IDLE to WAIT_FOR_ENDBRANCH state. In WAIT_FOR_ENDBRANCH state the next

intel

instruction in the program stream must be an ENDBRANCH. If an ENDBRANCH is not seen the processor causes a control protection fault (#CP), otherwise the state machine moves back to IDLE state.

More information on Intel® CET can be found at:

[https://software.intel.com/sites/default/files/managed/4d/2a/control-flow](https://software.intel.com/sites/default/files/managed/4d/2a/control-flow-enforcement-technology-preview.pdf)[enforcement-technology-preview.pdf](https://software.intel.com/sites/default/files/managed/4d/2a/control-flow-enforcement-technology-preview.pdf)

KeyLocker Technology 2.3.14

A method to make long-term keys short-lived without exposing them. This protects against vulnerabilities when keys can be exploited and used to attack encrypted data such as disk drives.

An instruction (LOADIWKEY) allows the OS to load a random wrapping value (IWKey). The IWKey can be backed up and restored by the OS to/from the PCH in a secure manner.

The Software can wrap it own key via the ENCODEKEY instruction and receive a handle. The handle is used with the AES*KL instructions to handle encrypt and decrypt operations. Once a handle is obtained, the software can delete the original key from memory.

Devil's Gate Rock 2.3.15

Devil's Gate Rock (DGR) is a BIOS hardening technology that splits SMI (System Management Interrupts) handlers into Ring 3 and Ring 0 portions.

Supervisor/user paging on the smaller Ring 0 portion will enforce access policy for all the ring 3 code with regard to the SMM state save, MSR registers, IO ports and other registers.

The Ring 0 portion can perform save/restore of register context to allow the Ring 3 section to make use of those registers without having access to the OS context or the ability to modify the OS context.

The Ring 0 portion is signed and provided by Intel. This portion is attested by the processor.

Power and Performance Technologies 2.4

Intel® Smart Cache Technology 2.4.1

The Intel[®] Smart Cache Technology is a shared Last Level Cache (LLC).

- The LLC is non-inclusive.
- The LLC may also be referred to as a 3rd level cache.
- The LLC is shared between all IA cores as well as the Processor Graphics.
- For P Cores The 1st and 2nd level caches are not shared between physical cores and each physical core has a separate set of caches.
- For E Cores The 1st level cache is not shared between physical cores and each physical core has a separate set of caches.

- For E Cores The 2nd level cache is shared between 4 physical cores.
- The size of the LLC is SKU specific with a maximum of 3MB per P physical core or 4 E cores and is a 12-way associative cache.

IA Cores Level 1 and Level 2 Caches 2.4.2

P Cores 1st level cache is divided into a data cache (DFU) and an instruction cache (IFU). The processor 1st level cache size is 48KB for data and 32KB for instructions. The 1st level cache is an 12-way associative cache.

E Cores 1st level cache is divided into a data cache (DFU) and an instruction cache (IFU). The processor 1st level cache size is 32KB for data and 64KB for instructions. The 1st level cache is an 8-way associative cache.

The 2nd level cache holds both data and instructions. It is also referred to as mid-level cache or MLC.

For P/H/H Refresh/U, S/HX 8P+8E, S 6P+0E predecessor lines, the P Cores 2nd level cache size is 1.25 MB and is a 10-way non-inclusive associative cache, 4 E Cores processors 2nd level cache size is 2MB and is a 16-way non-inclusive associative cache.

For S refresh 8P+8E, S refresh 6P+0E predecessor lines, the P Cores 2nd level cache size is 1.25 MB and is a 10-way non-inclusive associative cache, 4 E Cores processors 2nd level cache size is 2MB and is a 16-way non-inclusive associative cache.

For S/HX 8P+16E and E Processors Lines, the P Cores 2nd level cache size is2 MB and is a 16-way non-inclusive associative cache, 4 E Cores processors 2nd level cache size is 4MB and is a 16-way non-inclusive associative cache.

For S Refresh/HX Refresh 8P+16E Processors Lines, the P Cores 2nd level cache size is 2 MB and is a 16-way non-inclusive associative cache, 4 E Cores processors 2nd level cache size is 4MB and is a 16-way non-inclusive associative cache

Figure 11. Hybrid Cache

NOTES

- 1. L1 Data cache (DCU) 48KB (P-core) 32KB (E-Core)
- 2. L1 Instruction cache (IFU) 32KB (P-Core) 64KB (E-Core)
- 3. MLC Mid Level Cache 2MB (P-Core) 4MB (shared by 4 E-Cores)

Ring Interconnect 2.4.3

The Ring is a high speed, wide interconnect that links the processor cores, processor graphics and the System Agent.

The Ring shares frequency and voltage with the Last Level Cache (LLC).

The Ring's frequency dynamically changes. Its frequency is relative to both processor cores and processor graphics frequencies.

Intel® Performance Hybrid Architecture 2.4.4

The processor contains two types of cores, denoted as P-Cores and E-Cores (P core is a Performance core and E core is efficient core).

The P-Cores and E-Cores share the same instruction set.

The available instruction sets, when hybrid computing is enabled, is limited compared to the instruction sets available to P-Cores.

P core and E core frequency's will be determined by the processor algorithmic, to maximize performance and power optimization.

The following instruction sets are available only when the P-Core are enabled:

• FP16 support

For more details, refer to: [https://www.intel.com/content/www/us/en/developer/](HTTPS://WWW.INTEL.COM/CONTENT/WWW/US/EN/DEVELOPER/ARTICLES/TECHNICAL/HYBRID-ARCHITECTURE.HTML) [articles/technical/hybrid-architecture.html](HTTPS://WWW.INTEL.COM/CONTENT/WWW/US/EN/DEVELOPER/ARTICLES/TECHNICAL/HYBRID-ARCHITECTURE.HTML)

NOTE

Hybrid Computing may not be available on all SKUs.

Intel® Turbo Boost Max Technology 3.0 2.4.5

The Intel® Turbo Boost Max Technology 3.0 (ITBMT 3.0) grants a different maximum Turbo frequency for individual processor cores.

To enable ITBMT 3.0 the processor exposes individual core capabilities; including diverse maximum turbo frequencies.

An operating system that allows for varied per core frequency capability can then maximize power savings and performance usage by assigning tasks to the faster cores, especially on low core count workloads.

Processors enabled with these capabilities can also allow software (most commonly a driver) to override the maximum per-core Turbo frequency limit and notify the operating system via an interrupt mechanism.

For more information on the Intel[®] Turbo Boost Max 3.0 Technology, refer to [http://](http://www.intel.com/content/www/us/en/architecture-and-technology/turbo-boost/turbo-boost-max-technology.html) [www.intel.com/content/www/us/en/architecture-and-technology/turbo-boost/turbo](http://www.intel.com/content/www/us/en/architecture-and-technology/turbo-boost/turbo-boost-max-technology.html)[boost-max-technology.html](http://www.intel.com/content/www/us/en/architecture-and-technology/turbo-boost/turbo-boost-max-technology.html)

NOTE

Intel® Turbo Boost Max 3.0 Technology may not be available on all SKUs.

Power Aware Interrupt Routing (PAIR) 2.4.6

The processor includes enhanced power-performance technology that routes interrupts to threads or processor IA cores based on their sleep states. As an example, for energy savings, it routes the interrupt to the active processor IA cores without waking the deep idle processor IA cores. For performance, it routes the interrupt to the idle (C1) processor IA cores without interrupting the already heavily loaded processor IA cores. This enhancement is most beneficial for high-interrupt scenarios like Gigabit LAN, WLAN peripherals, etc.

Intel® Hyper-Threading Technology 2.4.7

The processor supports Intel® Hyper-Threading Technology (Intel® HT Technology) that allows an execution processor IA core to function as two logical processors. While some execution resources such as caches, execution units, and buses are shared, each logical processor has its own architectural state with its own set of generalpurpose registers and control registers. This feature should be enabled using the BIOS and requires operating system support.

Intel recommends enabling Intel® Hyper-Threading Technology with Microsoft* Windows* 7 or newer and disabling Intel® Hyper-Threading Technology using the BIOS for all previous versions of Windows* operating systems.

NOTE

Intel® HT Technology may not be available on all SKUs.

Intel® Turbo Boost Technology 2.0 2.4.8

The Intel® Turbo Boost Technology 2.0 allows the processor IA core/processor graphics core to opportunistically and automatically run faster than the processor IA core base frequency/processor graphics base frequency if it is operating below power, temperature, and current limits. The Intel® Turbo Boost Technology 2.0 feature is designed to increase the performance of both multi-threaded and single-threaded workloads.

Compared with previous generation products, Intel® Turbo Boost Technology 2.0 will increase the ratio of application power towards Processor Base Power (a.k.a TDP) and also allows to increase power above Processor Base Power (a.k.a TDP) as high as PL2 for short periods of time. Thus, thermal solutions and platform cooling that are

designed to less than thermal design guidance might experience thermal and performance issues since more applications will tend to run at the maximum power limit for significant periods of time.

NOTE

Intel® Turbo Boost Technology 2.0 may not be available on all SKUs.

Intel® Turbo Boost Technology 2.0 Frequency 2.4.8.1

To determine the highest performance frequency amongst active processor IA cores, the processor takes the following into consideration:

- The number of processor IA cores operating in the C0 state.
- The estimated processor IA core current consumption and ICCMax settings.
- The estimated package prior and present power consumption and turbo power limits.
- The package temperature.

Any of these factors can affect the maximum frequency for a given workload. If the power, current, or thermal limit is reached, the processor will automatically reduce the frequency to stay within its Processor Base Power (a.k.a TDP) limit. Turbo processor frequencies are only active if the operating system is requesting the P0 state. For more information on P-states and C-states, refer to [Power Management](#page-61-0) on page 62.

Intel® Turbo Boost Technology 2.0 Power Control 2.4.8.2

Illustration of Intel® Turbo Boost Technology 2.0 power control is shown in the following sections and figures. Multiple controls operate simultaneously allowing customization for multiple systems thermal and power limitations. These controls allow for turbo optimizations within system constraints and are accessible using MSR, MMIO, and PECI interfaces.

Intel® Turbo Boost Technology 2.0 Power Monitoring 2.4.8.3

When operating in turbo mode, the processor monitors its own power and adjusts the processor and graphics frequencies to maintain the average power within limits over a thermally significant time period. The processor estimates the package power for all components on the package. In the event that a workload causes the temperature to exceed program temperature limits, the processor will protect itself using the Adaptive Thermal Monitor.

Enhanced Intel SpeedStep® Technology 2.4.9

Enhanced Intel SpeedStep® Technology enables OS to control and select P-state. The following are the key features of Enhanced Intel SpeedStep® Technology:

- Multiple frequencies and voltage points for optimal performance and power efficiency. These operating points are known as P-states.
- Frequency selection is software controlled by writing to processor MSRs. The voltage is optimized based on the selected frequency and the number of active processors IA cores.
	- Once the voltage is established, the PLL locks on to the target frequency.

- — All active processor IA cores share the same frequency and voltage. In a multi-core processor, the highest frequency P-state requested among all active IA cores is selected.
- Software-requested transitions are accepted at any time. If a previous transition is in progress, the new transition is deferred until the previous transition is completed.
- The processor controls voltage ramp rates internally to ensure glitch-free transitions.

NOTE

Because there is low transition latency between P-states, a significant number of transitions per-second are possible.

Intel® Thermal Velocity Boost (Intel® TVB) 2.4.10

Intel[®] Thermal Velocity Boost allows the processor IA core to opportunistically and automatically increase the Intel® Turbo Boost Technology 2.0 frequency speed bins whenever processor temperature and voltage allows.

The Intel® Thermal Velocity Boost feature is designed to increase performance of both multi-threaded and singlethreaded workloads.

NOTE

Intel[®] Thermal Velocity Boost (Intel[®] TVB) may not be available on all SKUs.

Intel® Speed Shift Technology 2.4.11

Intel® Speed Shift Technology is an energy efficient method of frequency control by the hardware rather than relying on OS control. OS is aware of available hardware Pstates and requests the desired P-state or it can let the hardware determine the Pstate. The OS request is based on its workload requirements and awareness of processor capabilities. Processor decision is based on the different system constraints for example Workload demand, thermal limits while taking into consideration the minimum and maximum levels and activity window of performance requested by the Operating System.

Intel® Advanced Vector Extensions 2 (Intel® AVX2) 2.4.12

Intel® Advanced Vector Extensions 2.0 (Intel® AVX2) is the latest expansion of the Intel instruction set. Intel® AVX2 extends the Intel® Advanced Vector Extensions (Intel® AVX) with 256-bit integer instructions, floating-point fused multiply-add (FMA) instructions, and gather operations. The 256-bit integer vectors benefit math, codec, image, and digital signal processing software. FMA improves performance in face detection, professional imaging, and high-performance computing. Gather operations increase vectorization opportunities for many applications. In addition to the vector extensions, this generation of Intel processors adds new bit manipulation instructions useful in compression, encryption, and general purpose software. For more information on Intel® AVX, refer to http://www.intel.com/software/avx

Intel® Advanced Vector Extensions (Intel® AVX) are designed to achieve higher throughput to certain integer and floating point operation. Due to varying processor power characteristics, utilizing AVX instructions may cause a) parts to operate below the base frequency b) some parts with Intel[®] Turbo Boost Technology 2.0 to not achieve any or maximum turbo frequencies. Performance varies depending on hardware, software and system configuration and you should consult your system manufacturer for more information.

Intel® Advanced Vector Extensions refers to Intel® AVX or Intel® AVX2 .

For more information on Intel® AVX, refer to [https://software.intel.com/en-us/isa](https://software.intel.com/en-us/isa-extensions/intel-avx)[extensions/intel-avx.](https://software.intel.com/en-us/isa-extensions/intel-avx)

NOTE

Intel® AVX and AVX2 Technologies may not be available on all SKUs.

Intel® AVX2 Vector Neural Network Instructions (AVX2 VNNI) 2.4.12.1

Vector instructions for deep learning extension for AVX2.

NOTE

Intel® AVX and AVX2 Technologies may not be available on all SKUs.

Intel® 64 Architecture x2APIC 2.4.13

The x2APIC architecture extends the xAPIC architecture that provides key mechanisms for interrupt delivery. This extension is primarily intended to increase processor addressability.

Specifically, x2APIC:

- Retains all key elements of compatibility to the xAPIC architecture:
	- Delivery modes
	- Interrupt and processor priorities
	- Interrupt sources
	- Interrupt destination types
- Provides extensions to scale processor addressability for both the logical and physical destination modes
- Adds new features to enhance the performance of interrupt delivery
- Reduces the complexity of logical destination mode interrupt delivery on link based architectures

The key enhancements provided by the x2APIC architecture over xAPIC are the following:

- Support for two modes of operation to provide backward compatibility and extensibility for future platform innovations:
	- In xAPIC compatibility mode, APIC registers are accessed through memory mapped interface to a 4K-Byte page, identical to the xAPIC architecture.

- In the x2APIC mode, APIC registers are accessed through the Model Specific Register (MSR) interfaces. In this mode, the x2APIC architecture provides significantly increased processor addressability and some enhancements on interrupt delivery.
- Increased range of processor addressability in x2APIC mode:
	- Physical xAPIC ID field increases from 8 bits to 32 bits, allowing for interrupt processor addressability up to 4G-1 processors in physical destination mode. A processor implementation of x2APIC architecture can support fewer than 32 bits in a software transparent fashion.
	- Logical xAPIC ID field increases from 8 bits to 32 bits. The 32-bit logical x2APIC ID is partitioned into two sub-fields – a 16-bit cluster ID and a 16-bit logical ID within the cluster. Consequently, $((2^220) - 16)$ processors can be addressed in logical destination mode. Processor implementations can support fewer than 16 bits in the cluster ID sub-field and logical ID sub-field in a software agnostic fashion.
- More efficient MSR interface to access APIC registers:
	- To enhance inter-processor and self-directed interrupt delivery as well as the ability to virtualize the local APIC, the APIC register set can be accessed only through MSR-based interfaces in x2APIC mode. The Memory Mapped IO (MMIO) interface used by xAPIC is not supported in x2APIC mode.
- The semantics for accessing APIC registers have been revised to simplify the programming of frequently-used APIC registers by system software. Specifically, the software semantics for using the Interrupt Command Register (ICR) and End Of Interrupt (EOI) registers have been modified to allow for more efficient delivery and dispatching of interrupts.
- The x2APIC extensions are made available to system software by enabling the local x2APIC unit in the "x2APIC" mode. To benefit from x2APIC capabilities, a new operating system and a new BIOS are both needed, with special support for the x2APIC mode.
- The x2APIC architecture provides backward compatibility to the xAPIC architecture and forwards extensible for future Intel platform innovations.

NOTE

Intel® x2APIC Technology may not be available on all SKUs.

For more information, refer to the Intel® *64 Architecture x2APIC Specification* at <http://www.intel.com/products/processor/manuals/>

Intel® Dynamic Tuning Technology 2.4.14

Intel® Dynamic Tuning (Intel® DTT) consists of a set of software drivers and applications that allow a system manufacturer to optimize system performance and usability by:

- Dynamically optimize turbo settings of IA processors, power and thermal states of the platform for optimal performance
- Dynamically adjust the processor's peak power based on the current power delivery capability for optimal system usability
- Dynamically mitigate radio frequency interference for better RF throughput.

^R *Intel® Core™ and Xeon™ E 2400 Processors—Technologies*

Intel® GMM and Neural Network Accelerator 2.4.15

GNA stands for Gaussian Mixture Model and Neural Network Accelerator.

The GNA is used to process speech recognition without user training sequence. The GNA is designed to unload the processor cores and the system memory with complex speech recognition tasks and improve the speech recognition accuracy. The GNA is designed to compute millions of Gaussian probability density functions per second without loading the processor cores while maintaining low power consumption.

Cache Line Write Back 2.4.16

Writes back to memory the cache line (if dirty) that contains the linear address specified with the memory operand from any level of the cache hierarchy in the cache coherence domain. The line may be retained in the cache hierarchy in the nonmodified state. Retaining the line in the cache hierarchy is a performance optimization

(treated as a hint by hardware) to reduce the possibility of a cache miss on a subsequent access. Hardware may choose to retain the line at any of the levels in the cache hierarchy, and in some cases, may invalidate the line from the cache hierarchy. The source operand is a byte memory location.

The Cache Line Write Back (CLWB) instruction is documented in the Intel® Architecture Instruction Set Extensions Programming Reference (future architectures):

<https://software.intel.com/sites/default/files/managed/b4/3a/319433-024.pdf>

Remote Action Request 2.4.17

Remote Action Request (RAR) enables a significant speed up of several inter-processor operations by moving such operations from software (OS or application) to hardware.

The main feature is the speedup of TLB shootdowns.

A single RAR operation can invalidate multiple memory pages in the TLB.

A TLB (Translation Lookaside Buffer) is a per-core cache that holds mappings from virtual to physical addresses.

A TLB shootdown is the process of propagating a change in memory mapping (page table entry) to all the cores.

RAR supports the following operations:

- **Page Invalidation**: imitates the operation of performing INVLPG instructions corresponding or the TLB invalidation corresponding with "MOV CR3 / CR0"
- **Page Invalidation without CR3 Match:** identical to "Page invalidation", except that the processor does not check for a CR3 match
- **PCID Invalidation**: imitates the operation of performing INVPCID instructions
- **EPT Invalidation**: imitates the operation of performing INVEPT instructions
- **VPID Invalidation**: imitates the operation of performing INVVPID instructions
- **MSR Write**: imitates the operation of WRMSR instructions on all cores

User Mode Wait Instructions 2.4.18

The *UMONITOR* and *UMWAIT* are user mode (Ring 3) instructions similar to the supervisor mode (Ring 0) *MONITOR*/*MWAIT* instructions without the C-state management capability.

TPAUSE us an enhanced *PAUSE* instruction.

The mnemonics for the three new instructions are:

- **UMONITOR**: operates just like MONITOR but allowed in all rings.
- **UMWAIT**: allowed in all rings, and no specification of target C-state.
- **TPAUSE**: similar to *PAUSE* but with a software-specified delay. Commonly used in spin loops.

Intel® Adaptive Boost Technology 2.4.19

Intel[®] Adaptive Boost Technology (Intel[®] ABT) opportunistically increases the multicore turbo frequency while operating within IccMAX and temperature spec limitations.

Intel[®] ABT opportunistically delivers in-spec performance gains that are incremental to existing Turbo technologies. In systems equipped with performance spec power delivery, Intel® ABT allows additional multi-core turbo frequency while still operating within specified current and temperature limits.

NOTE

Intel Adaptive Boost technology may not be available on all SKUs.

Intel® Image Processing Unit 2.5

Platform Imaging Infrastructure 2.5.1

The platform imaging infrastructure is based on the following hardware components:

- **Camera Subsystem**: Located in the lid of the system and contains CMOS sensor, flash, LED, I/O interface (MIPI* CSI-2 and I2C*), focus control and other components.
- **Camera I/O Controller**: The I/O controller is located in the processor and contains a MIPI-CSI2 host controller. The host controller is a PCI device (independent of the IPU device). The CSI-2 HCI brings imaging data from an external image into the system and provides a command and control channel for the image using I^2C .
- **Intel® IPU (Image Processing Unit)**: The IPU processes raw images captured by Bayer sensors. The result images are used by still photography and video capture applications (JPEG, H.264, and so on.).

Figure 12. Processor Camera System

intel

Intel® Image Processing Unit 2.5.2

IPU6 is Intel's 6th generation solution for an Imaging Processing Unit, providing advanced imaging functionality for Intel® Core™ branded processors, as well as more specialized functionality for High Performance Mobile Phones, Automotive, Digital Surveillance Systems (DSS), and other market segments.

IPU6 is a continuing evolution of the architecture introduced in IPU4 and enhanced in IPU5. Additional image quality improvements are introduced, as well as hardware accelerated support for temporal de-noising and new sensor technologies such as Spatially Variant Exposure HDR and Dual Photo Diode, among others.

IPU6 provides a complete high quality hardware accelerated pipeline, and is therefore not dependent on algorithms running on the vector processors to provide the highest quality output.

• Processor Line has a lighter version of the IPU

Debug Technologies 2.6

Intel® Processor Trace 2.6.1

Intel[®] Processor Trace (Intel[®] PT) is a tracing capability added to Intel[®] Architecture, for use in software debug and profiling. Intel[®] PT provides the capability for more precise software control flow and timing information, with limited impact on software execution. This provides an enhanced ability to debug software crashes, hangs, or other anomalies, as well as responsiveness and short-duration performance issues.

Intel® VTune™ Amplifier for Systems and the Intel® System Debugger are part of Intel® System Studio 2015 (and newer) product, which includes updates for the new debug and trace features, including Intel® PT and Intel® Trace Hub.

Intel® System Studio 2015 is available for download at [https://software.intel.com/en](https://software.intel.com/en-us/system-studio)[us/system-studio](https://software.intel.com/en-us/system-studio).

An update to the Linux* performance utility, with support for Intel[®] PT, is available for download at https://github.com/virtuoso/linux-perf/tree/intel_pt. It requires rebuilding the kernel and the perf utility.

Platform CrashLog 2.6.2

- The CrashLog feature is intended for use by system builders (OEMs) as a means to triage and perform first level debug of failures.
- CrashLog enables the BIOS or the OS to collect data on failures with the intent to collect and classify the data as well as analyze failure trends.
- CrashLog is a mechanism to collect debug information into a single location and then allow access to that data via multiple methods, including the BIOS and OS of the failing system.
- CrashLog is initiated by a Crash Data Detector on observation of error conditions (TCO watchdog timeout, machine check exceptions, etc.).

- Crash Data Detector notifies the Crash Data Requester of the error condition in order for the Crash Data Requester to collect Crash Data from several different IPs and/or Crash Nodes and stores the data to the Crash Data Storage (on-die SRAM) prior to the reset.
- After the system has rebooted, the Crash Data Collector reads the Crash Data from the Crash Data Storage and makes the data available to either to software and/or back to a central server to track error frequency and trends.

Telemetry Aggregator 2.6.3

The Telemetry Aggregator serves as an architectural and discoverable interface to hardware telemetry:

- Standardized PCIe discovery solution that enables software to discover and manage telemetry across products
- Standardized definitions for telemetry decode, including data type definitions
- Exposure of commonly used telemetry for power and performance debug including:
	- P-State status, residency and counters
	- C-State status, residency and counters
	- Energy monitoring
	- Device state monitoring (for example, PCIe L1)
	- Interconnect/bus bandwidth counters
	- Thermal monitoring

Exposure of SoC state snapshot for atomic monitoring of package power states, uninterrupted by software that reads.

The Telemetry Aggregator is also a companion to the CrashLog feature where data is captured about the SoC at the point of a crash. These counters can provide insights into the nature of the crash.

^R *Intel® Core™ and Xeon™ E 2400 Processors—Technologies*

Figure 13. Telemetry Aggregator

Clock Topology 2.7

The processor has 3 reference clocks that drive the various components within the SoC:

- Processor reference clock or base clock (BCLK). 100MHz with SSC.
- PCIe reference clock (PCTGLK). 100MHz with SSC.
- Fixed clock. 38.4MHz without SSC (crystal clock).

BCLK drives the following clock domains:

- Core
- Ring
- Graphics (GT)
- Memory Controller (MC)
- System Agent (SA)

PCTGLK drives the following clock domains:

- PCIe Controller(s)
- DMI/OPIO

Fixed clock drives the following clock domains:

- Display
- SVID controller
- Time Stamp Counters (TSC)
- Type C subsystem

Integrated Reference Clock PLL 2.7.1

The processor includes a phase lock loop (PLL) that generates the reference clock for the processor from a fixed crystal clock. The processor reference clock is also referred to as Base Clock or BCLK.

By integrating the BCLK PLL into the processor die, a cleaner clock is achieved at a lower power compared to the legacy PCH BCLK PLL solution.

The BCLK PLL has controls for RFI/EMI mitigations as well as Overclocking capabilities.

Intel Volume Management Device Technology 2.8

Objective

Standard Operating Systems generally recognize individual PCIe Devices and load individual drivers. This is undesirable in some cases such as, for example, when there are several PCIe-based hard-drives connected to a platform where the user wishes to configure them as part of a RAID array. The Operating System current treats individual hard-drives as separate volumes and not part of a single volume.

In other words, the Operating System requires multiple PCIe devices to have multiple driver instances, making volume management across multiple host bus adapters (HBAs) and driver instances difficult.

Intel Volume Management Device (VMD) technology provides a means to provide volume management across separate PCI Express HBAs and SSDs without requiring operating system support or communication between drivers. For example, the OS will see a single RAID volume instead of multiple storage volumes, when Volume Management Device is used.

Overview

Intel Volume Management Device technology does this by obscuring each storage controller from the OS, while allowing a single driver to be loaded that would control each storage controller.

Intel Volume Management technology requires support in BIOS and driver, memory and configuration space management.

A Volume Management Device (VMD) exposes a single device to the operating system, which will load a single storage driver. The VMD resides in the processor's PCIe root complex and it appears to the OS as a root bus integrated endpoint. In the processor, the VMD is in a central location to manipulate access to storage devices which may be attached directly to the processor or indirectly through the PCH. Instead of allowing individual storage devices to be detected by the OS and therefore causing the OS to load a separate driver instance for each, VMD provides configuration settings to allow specific devices and root ports on the root bus to be invisible to the OS.

Access to these hidden target devices is provided by the VMD to the single, unified driver.

Features Supported

Supports MMIO mapped Configuration Space (CFGBAR):

- Supports MMIO Low
- Supports MMIO High
- Supports Register Lock or Restricted Access

- Supports Device Assign
- Function Assign
- MSI Remapping Disable

Deprecated Technologies 2.9

The processor has deprecated the following technologies and they are no longer supported:

- Intel[®] Memory Protection Extensions (Intel[®] MPX)
- Branch Monitoring Counters
- Hardware Lock Elision (HLE), part of Intel[®] TSX-NI
- Intel[®] Software Guard Extensions (Intel[®] SGX)
- Intel[®] TSX-NI
- Power Aware Interrupt Routing (PAIR)
- DDR Running Average Power Limit (DDR RAPL)

Processor Lines that support **Intel's Performance Hybrid Architecture** do not support the following:

• Intel[®] Advanced Vector Extensions 512 Bit

3.0 Power Management

Figure 14. Processor Package and IA Core C-States

- 1. PkgC2/C3 are non-architectural: software cannot request to enter these states explicitly. These states are intermediate states between PkgC0 and PkgC6.
- 2. There are constraints that prevent the system to go deeper.
- 3. The "core state" relates to the core which is in the HIGEST power state in the package (most active).

Advanced Configuration and Power Interface (ACPI) States Supported 3.1

This section describes the ACPI states supported by the processor.

Table 4. System States

13th Generation Intel® Core™, Intel® Core™ 14th Generation, Intel® Core™ Processor (Series 1) and (Series 2), and Intel® Xeon™ E 2400 Processor December 2024 Datasheet, Volume 1 of 2

intel

Table 5. Integrated Memory Controller (IMC) States

Table 6. G, S, and C Interface State Combinations

NOTE

1. PkgC2/C3 are non-architectural: software cannot request to enter these states explicitly. These states are intermediate states between PkgC0 and PkgC6.

Processor IA Core Power Management 3.2

While executing code, Enhanced Intel SpeedStep® Technology and Intel® Speed Shift technology optimizes the processor's IA core frequency and voltage based on workload. Each frequency and voltage operating point is defined by ACPI as a P-state. When the processor is not executing code, it is idle. A low-power idle state is defined by ACPI as a C-state. In general, deeper power C-states have longer entry and exit latencies.

OS/HW Controlled P-states 3.2.1

Enhanced Intel SpeedStep® Technology 3.2.1.1

Enhanced Intel SpeedStep® Technology enables OS to control and select P-state. For more information, refer to [Enhanced Intel SpeedStep](#page-47-0)® Technology on page 48.

Intel® Speed Shift Technology 3.2.1.2

Intel® Speed Shift Technology is an energy efficient method of frequency control by the hardware rather than relying on OS control. For more details, refer to [Intel](#page-48-0)® [Speed Shift Technology o](#page-48-0)n page 49.

Low-Power Idle States 3.2.2

When the processor is idle, low-power idle states (C-states) are used to save power. More power savings actions are taken for numerically higher C-states. However, deeper C-states have longer exit and entry latencies. Resolution of C-states occurs at the thread, processor IA core, and processor package level.

CAUTION

Long-term reliability cannot be assured unless all the Low-Power Idle States are enabled.

Figure 15. Idle Power Management Breakdown of the Processor IA Cores

While individual threads can request low-power C-states, power saving actions only take place once the processor IA core C-state is resolved. processor IA core C-states are automatically resolved by the processor. For thread and processor IA core Cstates, a transition to and from C0 state is required before entering any other C-state.

Requesting the Low-Power Idle States 3.2.3

The primary software interfaces for requesting low-power idle states are through the MWAIT instruction with sub-state hints and the HLT instruction (for C1 and C1E). However, the software may make C-state requests using the legacy method of I/O reads from the ACPI-defined processor clock control registers, referred to as P_LVLx. This method of requesting C-states provides legacy support for operating systems that initiate C-state transitions using I/O reads.

For legacy operating systems, P_LVLx I/O reads are converted within the processor to the equivalent MWAIT C-state request. Therefore, P_LVLx reads do not directly result in I/O reads to the system. The feature, known as I/O MWAIT redirection, should be enabled in the BIOS..

The BIOS can write to the C-state range field of the PMG_IO_CAPTURE MSR to restrict the range of I/O addresses that are trapped and emulate MWAIT like functionality. Any P_LVLx reads outside of this range do not cause an I/O redirection to MWAIT(Cx) like the request. They fall through like a normal I/O instruction.

When P_LVLx I/O instructions are used, MWAIT sub-states cannot be defined. The MWAIT sub-state is always zero if I/O MWAIT redirection is used. By default, P_LVLx I/O redirections enable the MWAIT 'break on EFLAGS.IF' feature that triggers a wake up on an interrupt, even if interrupts are masked by EFLAGS.IF.

Processor IA Core C-State Rules 3.2.4

The following are general rules for all processor IA core C-states unless specified otherwise:

- A processor IA core C-State is determined by the lowest numerical thread state (such as Thread 0 requests C1E while Thread 1 requests C6 state, resulting in a processor IA core C1E state). Refer to G, S, and C Interface State Combinations table.
- A processor IA core transitions to C0 state when:
	- An interrupt occurs
	- There is an access to the monitored address if the state was entered using an MWAIT/Timed MWAIT instruction
	- The deadline corresponding to the Timed MWAIT instruction expires
- An interrupt directed toward a single thread wakes up only that thread.
- If any thread in a processor IA core is active (in C0 state), the core's C-state will resolve to C0.
- Any interrupt coming into the processor package may wake any processor IA core.
- A system reset re-initializes all processor IA cores.

Table 7. Core C-states

Core C-State Auto-Demotion

In general, deeper C-states, such as C6, have long latencies and have higher energy entry/exit costs. The resulting performance and energy penalties become significant when the entry/exit frequency of a deeper C-state is high. Therefore, incorrect or inefficient usage of deeper C-states have a negative impact on battery life and idle power. To increase residency and improve battery life and idle power in deeper Cstates, the processor supports C-state auto-demotion.

C-State auto-demotion:

• C6 to C1/C1E

The decision to demote a processor IA core from C6 to C1/C1E is based on each processor IA core's immediate residency history. Upon each processor IA core C6 request, the processor IA core C-state is demoted to C1 until a sufficient amount of residency has been established. At that point, a processor IA core is allowed to go into C6 . If the interrupt rate experienced on a processor IA core is high and the processor IA core is rarely in a deep C-state between such interrupts, the processor IA core can be demoted to a C1 state.

This feature is disabled by default. BIOS should enable it in the PMG_CST_CONFIG_CONTROL register. The auto-demotion policy is also configured by this register.

Package C-States 3.2.5

The processor supports C0, C2, C3, C6, C8, and C10 package states. The following is a summary of the general rules for package C-state entry. These apply to all package Cstates, unless specified otherwise:

- A package C-state request is determined by the lowest numerical processor IA core C-state amongst all processor IA cores.
- A package C-state is automatically resolved by the processor depending on the processor IA core idle power states and the status of the platform components.
	- Each processor IA core can be at a lower idle power state than the package if the platform does not grant the processor permission to enter a requested package C-state.
	- The platform may allow additional power savings to be realized in the processor.

intel

- For package C-states, the processor is not required to enter C0 before entering any other C-state.
- Entry into a package C-state may be subject to auto-demotion that is, the processor may keep the package in a deeper package C-state then requested by the operating system if the processor determines, using heuristics, that the deeper C-state results in better power/performance.

The processor exits a package C-state when a break event is detected. Depending on the type of break event, the processor does the following:

- If a processor IA core break event is received, the target processor IA core is activated and the break event message is forwarded to the target processor IA core.
	- If the break event is not masked, the target processor IA core enters the processor IA core C0 state and the processor enters package C0.
	- If the break event is masked, the processor attempts to re-enter its previous package state.
- If the break event was due to a memory access or snoop request,
	- But the platform did not request to keep the processor in a higher package Cstate, the package returns to its previous C-state.
	- And the platform requests a higher power C-state, the memory access or snoop request is serviced and the package remains in the higher power Cstate.

Figure 16. Package C-State Entry and Exit

PKG C2 and C3 can not be requested explicitly by the software

Table 8. Package C-States

Note: Display In PSR is only on single embedded panel configuration and panel support PSR feature.

Package C-State Auto-Demotion

The Processor may demote the Package C-State to a shallower Package C-State to enable better performance, for example instead of going into Package C10, processor will demote to Package C6 (and shallower as required).

The processor's decision to demote the Package C-State is based on Power management parameters such as required C states latencies, entry/exit energy/power, Core wake rates, and device LTR (Latency Tolerance Report). This means that the processor is optimized to minimize platform energy for scenarios with low idle time.

intel

Processor deeper Package C-State entry frequency is controlled to minimize platform energy. When Package C-State Auto-Demotion enabled, a reduced residency in a deeper Package C-State is expected during system runs with high wake rates.

No change at IDLE scenario power consumption due to this feature. Package C-State Auto-Demotion is enabled by default and controlled through BIOS menu.

Modern Standby

Modern Standby is a platform state. On display time out the OS requests the processor to enter package C10 and platform devices at RTD3 (or disabled) in order to attain low power in idle. Modern Standby requires proper BIOS and OS configuration.

Dynamic LLC Sizing

When all processor IA cores request C8 or deeper C-state, internal heuristics dynamically flushes the LLC. Once the processor IA cores enter a deep C-state, depending on their MWAIT sub-state request, the LLC is either gradually flushed Nways at a time or flushed all at once. Upon the processor IA cores exiting to C0 state, the LLC is gradually expanded based on internal heuristics.

Package C-States and Display Resolutions 3.2.6

The integrated graphics engine has the frame buffer located in system memory. When the display is updated, the graphics engine fetches display data from system memory. Different screen resolutions and refresh rates have different memory latency requirements. These requirements may limit the deepest Package C-state the processor can enter. Other elements that may affect the deepest Package C-state available are the following:

- Display is on or off
- Single or multiple displays
- Native or non-native resolution
- Panel Self Refresh (PSR) technology

NOTE

Display resolution is not the only factor influencing the deepest Package C-state the processor can get into. Device latencies, interrupt response latencies, and core Cstates are among other factors that influence the final package C-state the processor can enter.

Processor AUX Power Management 3.3

VCCIN AUX IMON Feature

This feature is the new power feature which allows the processor to read VCCIN Aux average current via the IMVP9.1 controller over SVID.

It allows the processor to get an accurate power estimation of VCCIN Aux, which is reflected in more accurate package power reporting and better accuracy in meeting the package power limits (PL1, PL2, and PL3).

VCCIN Aux IMON CPU strap will be enabled by default for best performance and power.

Processor Graphics Power Management 3.4

Memory Power Savings Technologies 3.4.1

Intel® Rapid Memory Power Management (Intel® RMPM)

Intel® Rapid Memory Power Management (Intel® RMPM) conditionally places memory into self-refresh when the processor is in package C3 or deeper power state to allow the system to remain in the deeper power states longer for memory not reserved for graphics memory. Intel® RMPM functionality depends on graphics/display state (relevant only when processor graphics is being used), as well as memory traffic patterns generated by other connected I/O devices.

Display Power Savings Technologies 3.4.2

Intel® Seamless Display Refresh Rate Switching Technology (Intel® SDRRS Technology) with eDP* Port

Intel® DRRS provides a mechanism where the monitor is placed in a slower refresh rate (the rate at which the display is updated). The system is smart enough to know that the user is not displaying either 3D or media like a movie where specific refresh rates are required. The technology is very useful in an environment such as a plane where the user is in battery mode doing E-mail, or other standard office applications. It is also useful where the user may be viewing web pages or social media sites while in battery mode.

Intel® OLED Power Saving Technology (Intel® OPST) 1.1

Intel[®] OPST solution uses same HW infrastructure as Intel[®] DPST. Frames are processed using frame change threshold based interrupt mechanism similar to Intel® DPST. Intel® OPST SW algorithm determines which pixels in the frame should be dimmed to save power keeping visual quality (such as contrast, color) impact to acceptable level. Since there is no backlight for OLED panels, the power savings come solely from pixel dimming.

Intel® Display Power Saving Technology (Intel® DPST)

The Intel® DPST technique achieves back-light power savings while maintaining a good visual experience. This is accomplished by adaptively enhancing the displayed image while decreasing the back-light brightness simultaneously. The goal of this technique is to provide equivalent end-user-perceived image quality at a decreased back-light power level.

- 1. The original (input) image produced by the operating system or application is analyzed by the Intel® DPST subsystem. An interrupt to Intel® DPST software is generated whenever a meaningful change in the image attributes is detected. (A meaningful change is when the Intel® DPST determines if the brightness of the displaying images and the image enhancement and back-light control needs to be altered.)
- 2. Intel[®] DPST subsystem applies an image-specific enhancement to increase image brightness.

3. A corresponding decrease to the back-light brightness is applied simultaneously to produce an image with similar user-perceived quality (such as brightness) as the original image.

Intel® DPST 7.1 has improved power savings without adversely affecting the performance.

NOTE

13th Generation Intel® Core™ processor uses Intel® DPST 7.1 while Intel® Core™ 14th Generation Processors uses Intel® DPST 8.0

Panel Self-Refresh 2 (PSR 2)

Panel Self-Refresh feature allows the Processor Graphics core to enter low-power state when the frame buffer content is not changing constantly. This feature is available on panels capable of supporting Panel Self-Refresh. Apart from being able to support, the eDP* panel should be eDP 1.4 compliant. PSR 2 adds partial frame updates and requires an eDP 1.4 compliant panel.

Low-Power Single Pipe (LPSP)

Low-power single pipe is a power conservation feature that helps save power by keeping the inactive pipes powered OFF. LPSP is achieved by keeping a pipe enabled during eDP* only with minimal display pipeline support.

Low-Power Dual Pipe (LPDP)

This feature is similar to LPSP and is applicable for designs with dual eDP* panels.

Intel® Smart 2D Display Technology (Intel® S2DDT)

Intel® S2DDT reduces display refresh memory traffic by reducing memory reads required for display refresh. Power consumption is reduced by less accesses to the IMC. Intel S2DDT is only enabled in single pipe mode.

Intel® S2DDT is most effective with:

- Display images well suited to compression, such as text windows, slide shows, and so on. Poor examples are 3D games.
- Static screens such as screens with significant portions of the background showing 2D applications, processor benchmarks, and so on, or conditions when the processor is idle. Poor examples are full-screen 3D games and benchmarks that flip the display image at or near display refresh rates.

Processor Graphics Core Power Savings Technologies 3.4.3

Intel® Graphics Dynamic Frequency

Intel[®] Turbo Boost Technology 2.0 is the ability of the processor IA cores and graphics (Graphics Dynamic Frequency) cores to opportunistically increase frequency and/or voltage above the guaranteed processor and graphics frequency for the given part. Intel® Graphics Dynamic Frequency is a performance feature that makes use of unused package power and thermals to increase application performance. The increase in frequency is determined by how much power and thermal budget is available in the package, and the application demand for additional processor or graphics performance. The processor IA core control is maintained by an embedded

controller. The graphics driver dynamically adjusts between P-States to maintain optimal performance, power, and thermals. The graphics driver will always place the graphics engine in its lowest possible P-State. Intel® Graphics Dynamic Frequency requires BIOS support. Additional power and thermal budget should be available.

Intel® Graphics Render Standby Technology (Intel® GRST)

Intel® Graphics Render Standby Technology is a technique designed to optimize the average power of the graphics part. The Graphics Render engine will be put in a sleep state, or Render Standby (RS), during times of inactivity or basic video modes. While in Render Standby state, the graphics part will place the VR (Voltage Regulator) into a low voltage state. Hardware will save the render context to the allocated context buffer when entering RS state and restore the render context upon exiting RS state.

Intel Capped Frames Per Second (CFPS)

Intel Capped Frames Per Second is a feature developed to save power during High FPS Gaming workloads while also achieving a tear and stutter free visual experience.

This feature ensures that the frame rate of the game does not exceed the panel refresh rate by matching screen updates to the Vertical Sync. That results fewer wakeups of graphics core and saves power.

When enabled, this feature works on any display panel, AC or DC mode and on any gaming workload.

System Agent Enhanced Intel SpeedStep® Technology 3.5

System Agent Enhanced Intel SpeedStep® Technology is a dynamic voltage frequency scaling of the System Agent clock based on memory utilization. Unlike processor core and package Enhanced Intel SpeedStep® Technology, System Agent Enhanced Intel SpeedStep[®] Technology has three valid operating points. When running light workload and SA Enhanced Intel SpeedStep® Technology is enabled, the DDR data rate may change as follows:

BIOS/MRC DDR training at maximum, mid and minimum frequencies sets I/O and timing parameters.

In order to achieve the optimal levels of performance and power, the memory initialization and training process performed during first system boot or after CMOS clear or after a BIOS update will take a longer time than a typical boot. During this initialization and training process, end users may see a blank screen. More information on the memory initialization process can be found in the industry standard JEDEC Specifications found on **www.JEDEC.org.**

Before changing the DDR data rate, the processor sets DDR to self-refresh and changes the needed parameters. The DDR voltage remains stable and unchanged.

Rest Of Platform (ROP) PMIC 3.6

In addition to discrete voltage regulators, Intel supports specific PMIC (Power Management Integrated Circuit) models to power the ROP rails. PMICs are typically classified as "Premium" or "Volume" ROP PMICs.

PCI Express* Power Management 3.7

- Active power management support using L0s (see below), L1 Substates(L1.1,L1.2)
- L0s is supported across all PEG interfaces.
- All inputs and outputs disabled in L2/L3 Ready state.
- S Processor PCIe* interface does not support Hot-Plug.

NOTE

An increase in power consumption may be observed when PCI Express* ASPM capabilities are disabled.

Table 9. Package C-States with PCIe* Link States Dependencies

TCSS Power State 3.8

Table 10. TCSS Power State

4.0 Thermal Management

Processor Thermal Management 4.1

The thermal solution provides both component-level and system-level thermal management. To allow optimal operation and long-term reliability of Intel processorbased systems, the system/processor thermal solution should be designed so that the processor:

- Remains below the maximum junction temperature (T_{JMAX}) specification at the maximum Processor Base power (a.k.a TDP).
- Conforms to system constraints, such as system acoustics, system skintemperatures, and exhaust-temperature requirements.

CAUTION

Thermal specifications given in this chapter are on the component and package level and apply specifically to the processor. Operating the processor outside the specified limits may result in permanent damage to the processor and potentially other components in the system.

Thermal Considerations 4.1.1

The Processor Base Power (a.k.a TDP) is the assured sustained power that should be used for the design of the processor thermal solution, Design to a higher thermal capability will get more Turbo residency. Processor Base Power (a.k.a TDP) is the timeaveraged power dissipation that the processor is validated to not exceed during manufacturing while executing an Intel-specified high complexity workload at Base Frequency and at the maximum junction temperature for the SKU segment and configuration.

NOTE

The System on Chip processor integrates multiple compute cores and I/O on a single package. Platform support for specific usage experiences may require additional concurrency power to be considered when designing the power delivery and thermal sustained system capability.

The processor integrates multiple processing IA cores, graphics cores and for some SKUs a PCH on a single package. This may result in power distribution differences across the package and should be considered when designing the thermal solution.

Intel ® Turbo Boost Technology 2.0 allows processor IA cores to run faster than the base frequency. It is invoked opportunistically and automatically as long as the processor is conforming to its temperature, power, power delivery, and current control limits. When Intel® Turbo Boost Technology 2.0 is enabled:

- • The processor may exceed the Processor Base Power (a.k.a TDP) for short durations to utilize any available thermal capacitance within the thermal solution. The duration and time of such operation can be limited by platform runtime configurable registers within the processor.
- Graphics peak frequency operation is based on the assumption of only one of the graphics domains (GT/GTx) being active. This definition is similar to the IA core Turbo concept, where peak turbo frequency can be achieved when only one IA core is active. Depending on the workload being applied and the distribution across the graphics domains the user may not observe peak graphics frequency for a given workload or benchmark.
- Thermal solutions and platform cooling that is designed to less than thermal design guidance may experience thermal and performance issues.

NOTE

Intel® Turbo Boost Technology 2.0 availability may vary between the different SKUs.

Package Power Control 4.1.1.1

The package power control settings of PL1, PL2, PL3, PL4, and Tau allow the designer to configure Intel[®] Turbo Boost Technology 2.0 to match the platform power delivery and package thermal solution limitations.

- **Power Limit 1 (PL1)**: A threshold for average power that will not exceed recommend to set to equal Processor Base Power (a.k.a TDP). PL1 should not be set higher than thermal solution cooling limits.
- **Power Limit 2 (PL2)**: A threshold that if exceeded, the PL2 rapid power limiting algorithms will attempt to limit the spike above PL2.
- **Power Limit 3 (PL3)**: A threshold that if exceeded, the PL3 rapid power limiting algorithms will attempt to limit the duty cycle of spikes above PL3 by reactively limiting frequency. This is an optional setting
- **Power Limit 4 (PL4)**: A limit that will not be exceeded, the PL4 power limiting algorithms will preemptively limit frequency to prevent spikes above PL4.
- **Turbo Time Parameter (Tau)**: An averaging constant used for PL1 exponential weighted moving average (EWMA) power calculation.

NOTES

- 1. Implementation of Intel® Turbo Boost Technology 2.0 only requires configuring PL1, PL1, Tau and PL2.
- 2. The Turbo Implementation guide and BIOS Specification.
- 3. PL3 and PL4 are disabled by default.
- 4. The Intel Dynamic Tuning (DTT) is recommended for performance improvement in mobile platforms. Dynamic Tuning is configured by system manufacturers dynamically optimizing the processor power based on the current platform thermal and power delivery conditions. Contact Intel Representatives for enabling details.

intel

Figure 17. Package Power Control

Platform Power Control 4.1.1.2

The processor introduces Psys (Platform Power) to enhance processor power management. The Psys signal needs to be sourced from a compatible charger circuit and routed to the IMVP9.1 (voltage regulator). This signal will provide the total thermally relevant platform power consumption (processor and rest of platform) via SVID to the processor.

When the Psys signal is properly implemented, the system designer can utilize the package power control settings of PsysPL1, PsysPL1 Tau , PsysPL2, and PsysPL3 for additional manageability to match the platform power delivery and platform thermal solution limitations for Intel® Turbo Boost Technology 2.0. The operation of the PsysPL1, PsysPL1 Tau , PsysPL2 and PsysPL3 are analogous to the processor power limits described in [Package Power Control](#page-76-0) on page 77.

- **Platform Power Limit 1 (PsysPL1)**: A threshold for average platform power that will not be exceeded - recommend to set to equal platform thermal capability.
- **Platform Power Limit 2 (PsysPL2)**: A threshold that if exceeded, the PsysPL2 rapid power limiting algorithms will attempt to limit the spikes above PsysPL2.
- **Platform Power Limit 3 (PsysPL3)**: A threshold that if exceeded, the PsysPL3 rapid power limiting algorithms will attempt to limit the duty cycle of spikes above PsysPL3 by reactively limiting frequency.
- **PsysPL1 Tau**: An averaging constant used for PsysPL1 exponential weighted moving average (EWMA) power calculation.

- The Psys signal and associated power limits / Tau are optional for the system designer and disabled by default.
- The Psys data will not include power consumption for charging.
- The Intel Dynamic Tuning (DTT) is recommended for performance improvement in mobile platforms. Dynamic Tuning is configured by system manufacturers dynamically optimizing the processor power based on the current platform thermal and power delivery conditions. Contact Intel Representatives for enabling details.

Turbo Time Parameter (Tau) 4.1.1.3

Turbo Time Parameter (Tau) is a mathematical parameter (units of seconds) that controls the Intel[®] Turbo Boost Technology 2.0 algorithm. During a maximum power turbo event, the processor could sustain PL2 for a duration longer than the Turbo Time Parameter. If the power value and/or Turbo Time Parameter is changed during runtime, it may take some time based on the new Turbo Time Parameter level for the algorithm to settle at the new control limits. The time varies depending on the magnitude of the change, power limits and other factors. There is an individual Turbo Time Parameter associated with Package Power Control and Platform Power Control.

Assured Power (cTDP) 4.1.2

Assured Power (cTDP) form a design option where the processor's behavior and package Processor Base Power (a.k.a TDP) are dynamically adjusted to a desired system performance and power envelope. Assured Power (cTDP) and Low-Power Mode technologies offer opportunities to differentiate system design while running active workloads on select processor SKUs through scalability, configuration and adaptability. The scenarios or methods by which each technology is used are customizable but typically involve changes to PL1 and associated frequencies for the scenario with a resultant change in performance depending on system's usage. Either technology can be triggered by (but are not limited to) changes in OS power policies or hardware events such as docking a system, flipping a switch or pressing a button. Assured Power (cTDP) is designed to be configured dynamically and do not require an operating system reboot.

NOTE

Assured Power (cTDP) is not battery life improvement technologies.

Assured Power (cTDP) 4.1.2.1

NOTE

Assured Power (cTDP) availability may vary between the different SKUs.

With Assured Power (cTDP), the processor is capable of altering the maximum sustained power with an alternate processor IA core base frequency. Assured Power (cTDP) allows operation in situations where extra cooling is available or situations where a cooler and quieter mode of operation is desired.

cTDP consists of three modes as shown in the following table.

Table 11. Assured Power (cTDP) Modes

In each mode, the Intel[®] Turbo Boost Technology 2.0 power limits are reprogrammed along with a new OS controlled frequency range. The Intel Dynamic Tuning driver assists in Processor Base Power (a.k.a TDP) operation by adjusting processor PL1 dynamically. The Assured Power (cTDP) mode does not change the maximum perprocessor IA core turbo frequency.

Thermal Management Features 4.1.3

Occasionally the processor may operate in conditions that are near to its maximum operating temperature. This can be due to internal overheating or overheating within the platform. In order to protect the processor and the platform from thermal failure, several thermal management features exist to reduce package power consumption and thereby temperature in order to remain within normal operating limits. Furthermore, the processor supports several methods to reduce memory power.

Adaptive Thermal Monitor 4.1.3.1

The purpose of the Adaptive Thermal Monitor is to reduce processor IA core power consumption and temperature until it operates below its maximum operating temperature. Processor IA core power reduction is achieved by:

- Adjusting the operating frequency (using the processor IA core ratio multiplier) and voltage.
- Modulating (starting and stopping) the internal processor IA core clocks (duty cycle).

The Adaptive Thermal Monitor can be activated when the package temperature, monitored by any Digital Thermal Sensor (DTS), meets its maximum operating temperature. The maximum operating temperature implies maximum junction temperature Tj_{MAX}.

Reaching the maximum operating temperature activates the Thermal Control Circuit (TCC). When activated the TCC causes both the processor IA core and graphics core to reduce frequency and voltage adaptively. The Adaptive Thermal Monitor will remain active as long as the package temperature remains at its specified limit. Therefore, the Adaptive Thermal Monitor will continue to reduce the package frequency and voltage until the TCC is de-activated.

 T_{JMAX} is factory calibrated and is not user configurable. The default value is software visible in the TEMPERATURE_TARGET (0x1A2) MSR, bits [23:16].

The Adaptive Thermal Monitor does not require any additional hardware, software drivers, or interrupt handling routines. It is not intended as a mechanism to maintain processor thermal control to $PL1$ = Processor Base Power. The system design should provide a thermal solution that can maintain normal operation when PL1 = Processor Base Power within the intended usage range.

Adaptive Thermal Monitor protection is always enabled.

TCC Activation Offset

TCC Activation Offset can be set as an offset from TjMAX to lower the onset of TCC and Adaptive Thermal Monitor. In addition, there is an optional time window (Tau) to manage processor performance at the TCC Activation offset value via an EWMA (Exponential Weighted Moving Average) of temperature.

TCC Activation Offset with Tau=0

An offset (degrees Celsius) can be written to the TEMPERATURE TARGET ($0x1A2$) MSR, bits [29:24], the offset value will be subtracted from the value found in bits [23:16]. When the time window (Tau) is set to zero, there will be no averaging, the offset, will be subtracted from the TjMAX value and used as a new maximum temperature set point for Adaptive Thermal Monitoring. This will have the same behavior as in prior products to have TCC activation and Adaptive Thermal Monitor to occur at this lower target silicon temperature.

If enabled, the offset should be set lower than any other passive protection such as ACPI _PSV trip points

TCC Activation Offset with Tau

To manage the processor with the EWMA (Exponential Weighted Moving Average) of temperature, an offset (degrees Celsius) is written to the TEMPERATURE_TARGET (0x1A2) MSR, bits [29:24], and the time window (Tau) is written to the TEMPERATURE_TARGET (0x1A2) MSR [6:0]. The Offset value will be subtracted from the value found in bits [23:16] and be the temperature.

The processor will manage to this average temperature by adjusting the frequency of the various domains. The instantaneous Tj can briefly exceed the average temperature. The magnitude and duration of the overshoot is managed by the time window value (Tau).

This averaged temperature thermal management mechanism is in addition, and not instead of TjMAX thermal management. That is, whether the TCC activation offset is 0 or not, TCC Activation will occur at TjMAX.

Frequency / Voltage Control

intel

Upon Adaptive Thermal Monitor activation, the processor attempts to dynamically reduce processor temperature by lowering the frequency and voltage operating point. The operating points are automatically calculated by the processor IA core itself and do not require the BIOS to program them as with previous generations of Intel processors. The processor IA core will scale the operating points such that:

- The voltage will be optimized according to the temperature, the processor IA core bus ratio and the number of processor IA cores in deep C-states.
- The processor IA core power and temperature are reduced while minimizing performance degradation.

Once the temperature has dropped below the trigger temperature, the operating frequency and voltage will transition back to the normal system operating point.

Once a target frequency/bus ratio is resolved, the processor IA core will transition to the new target automatically.

- On an upward operating point transition, the voltage transition precedes the frequency transition.
- On a downward transition, the frequency transition precedes the voltage transition.
- The processor continues to execute instructions. However, the processor will halt instruction execution for frequency transitions.

If a processor load-based Enhanced Intel SpeedStep Technology/P-state transition (through MSR write) is initiated while the Adaptive Thermal Monitor is active, there are two possible outcomes:

- If the P-state target frequency is higher than the processor IA core optimized target frequency, the P-state transition will be deferred until the thermal event has been completed.
- If the P-state target frequency is lower than the processor IA core optimized target frequency, the processor will transition to the P-state operating point.

Clock Modulation

If the frequency/voltage changes are unable to end an Adaptive Thermal Monitor event, the Adaptive Thermal Monitor will utilize clock modulation. Clock modulation is done by alternately turning the clocks off and on at a duty cycle (ratio between clock "on" time and total time) specific to the processor. The duty cycle is factory configured to 25% on and 75% off and cannot be modified. The period of the duty cycle is configured to 32 microseconds when the Adaptive Thermal Monitor is active. Cycle times are independent of processor frequency. A small amount of hysteresis has been included to prevent excessive clock modulation when the processor temperature is near its maximum operating temperature. Once the temperature has dropped below the maximum operating temperature, and the hysteresis timer has expired, the Adaptive Thermal Monitor goes inactive and clock modulation ceases. Clock modulation is automatically engaged as part of the Adaptive Thermal Monitor activation when the frequency/voltage targets are at their minimum settings. Processor performance will be decreased when clock modulation is active. Snooping and interrupt processing are performed in the normal manner while the Adaptive Thermal Monitor is active.

Clock modulation will not be activated by the Package average temperature control mechanism.

Thermal Throttling

As the processor approaches TJMax a throttling mechanisms will engage to protect the processor from over-heating and provide control thermal budgets.

Achieving this is done by reducing IA and other subsystem agent's voltages and frequencies in a gradual and coordinated manner that varies depending on the dynamics of the situation. IA frequencies and voltages will be directed down as low as LFM (Lowest Frequency Mode). In rare extreme conditions the processor may slow down IO operations to prevent shutdown.

Further restricts are possible via Thermal Trolling point (TT1) under conditions where thermal budget cannot be re-gained fast enough with voltages and frequencies reduction alone. TT1 keeps the same processor voltage and clock frequencies the same yet skips clock edges to produce effectively slower clocking rates. This will effectively result in observed frequencies below LFM on the Windows PERF monitor.

Digital Thermal Sensor 4.1.3.2

Each processor has multiple on-die Digital Thermal Sensor (DTS) that detects the processor IA, GT and other areas of interest instantaneous temperature.

Temperature values from the DTS can be retrieved through:

- A software interface using processor Model Specific Register (MSR).
- A processor hardware interface.

When the temperature is retrieved by the processor MSR, it is the instantaneous temperature of the given DTS. When the temperature is retrieved using PECI, it is the average of the highest DTS temperature in the package over a 256 ms time window. Intel recommends using the PECI reported temperature for platform thermal control that benefits from averaging, such as fan speed control. The average DTS temperature may not be a good indicator of package Adaptive Thermal Monitor activation or rapid increases in temperature that triggers the Out of Specification status bit within the PACKAGE_THERM_STATUS (0x1B1) MSR and IA32_THERM_STATUS (0x19C) MSR.

Code execution is halted in C1 or deeper C-states. Package temperature can still be monitored through PECI in lower C-states.

Unlike traditional thermal devices, the DTS outputs a temperature relative to the maximum supported operating temperature of the processor (T_{MAX}) , regardless of TCC activation offset. It is the responsibility of software to convert the relative temperature to an absolute temperature. The absolute reference temperature is readable in the TEMPERATURE_TARGET (0x1A2) MSR. The temperature returned by the DTS is an implied negative integer indicating the relative offset from T_{MAX} . The DTS does not report temperatures greater than Tj_{MAX}. The DTS-relative temperature readout directly impacts the Adaptive Thermal Monitor trigger point. When a package DTS indicates that it has reached the TCC activation (a reading of 0x0, except when the TCC activation offset is changed), the TCC will activate and indicate an Adaptive Thermal Monitor event. A TCC activation will lower both processor IA core and graphics core frequency, voltage, or both. Changes to the temperature can be detected using two programmable thresholds located in the processor thermal MSRs. These thresholds have the capability of generating interrupts using the processor IA core's local APIC. Refer to the *Intel 64 Architectures Software Developer's Manual* for specific register and programming details.

Digital Thermal Sensor Accuracy (T_accuracy)

The error associated with DTS measurements will not exceed \pm 5 °C within the entire operating range.

Fan Speed Control with Digital Thermal Sensor

Digital Thermal Sensor based fan speed control (T_{FAN}) is a recommended feature to achieve optimal thermal performance. At the T_{FAN} temperature, Intel recommends full cooling capability before the DTS reading reaches T_{JMAX} .

PROCHOT# Signal 4.1.3.3

The PROCHOT# (processor hot) signal is asserted by the processor when the TCC is active. Only a single PROCHOT# pin exists at a package level. When any DTS temperature reaches the TCC activation temperature, the PROCHOT# signal will be asserted. PROCHOT# assertion policies are independent of Adaptive Thermal Monitor enabling.

The PROCHOT# signal can be configured to the following modes:

- **Input Only: PROCHOT is driven by an external device.**
- **Output Only: PROCHOT is driven by processor.**
- **Bi-Directional**: Both Processor and external device can drive PROCHOT signal

PROCHOT Input Only

The PROCHOT# signal should be set to input only by default. In this state, the processor will only monitor PROCHOT# assertions and respond by setting the maximum frequency to 10Khz.

The following two features are enabled when PROCHOT is set to Input only:

- **Fast PROCHOT**: Respond to PROCHOT# within 1uS of PROCHOT# pin assertion, reducing the processor power.
- **PROCHOT Demotion Algorithm**: designed to improve system performance during multiple PROCHOT assertions.

Figure 18. PROCHOT Demotion Description

PROCHOT Output Only 4.1.3.4

Legacy state, PROCHOT is driven by the processor to external device.

Bi-Directional PROCHOT# 4.1.3.5

By default, the PROCHOT# signal is set to input only. When configured as an input or bi-directional signal, PROCHOT# can be used for thermally protecting other platform components should they overheat as well. When PROCHOT# is driven by an external device:

- The package will immediately transition to the lowest P-State (Pn) supported by the processor IA cores and graphics cores. This is contrary to the internallygenerated Adaptive Thermal Monitor response.
- Clock modulation is not activated.

The processor package will remain at the lowest supported P-state until the system de-asserts PROCHOT#. The processor can be configured to generate an interrupt upon assertion and de-assertion of the PROCHOT# signal. Refer to the appropriate processor family BIOS Specification for specific register and programming details.

When PROCHOT $#$ is configured as a bi-directional signal and PROCHOT $#$ is asserted by the processor, it is impossible for the processor to detect a system assertion of PROCHOT#. The system assertion will have to wait until the processor de-asserts PROCHOT# before PROCHOT# action can occur due to the system assertion. While the processor is hot and asserting PROCHOT#, the power is reduced but the reduction rate is slower than the system PROCHOT# response of $<$ 100 us. The processor thermal control is staged in smaller increments over many milliseconds. This may cause several milliseconds of delay to a system assertion of PROCHOT# while the output function is asserted.

PROCHOT Demotion Algorithm 4.1.3.6

PROCHOT demotion algorithm is designed to improve system performance following multiple Platform PROCHOT consecutive assertions. During each PROCHOT assertion processor will eventually transition to the lowest P-State (Pn) supported by the processor IA cores and graphics cores (LFM). When detecting several PROCHOT consecutive assertions the processor will reduce the max frequency in order to reduce the PROCHOT assertions events. The processor will keep reducing the frequency until no consecutive assertions detected. The processor will raise the frequency if no consecutive PROCHOT assertion events will occur. PROCHOT demotion algorithm enabled only when the PROCHOT is configured as input.

NOTE

PROCHOT Demotion Algorithm is enabled by Hardware default only when the PROCHOT is configured as input. This feature can be disabled through BIOS policy. .

Voltage Regulator Protection using PROCHOT# 4.1.3.7

PROCHOT# may be used for thermal protection of voltage regulators (VR). System designers can create a circuit to monitor the VR temperature and assert PROCHOT# and, if enabled, activate the TCC when the temperature limit of the VR is reached. When PROCHOT $#$ is configured as a bi-directional or input only signal, if the system assertion of PROCHOT# is recognized by the processor, results in power reduction. Power reduction down to LFM and duration of the platform PROCHOT# assertion as described in paragraph 4.1.3.6. supported by the processor IA cores and graphics cores. Systems should still provide proper cooling for the VR and rely on bi-directional PROCHOT# only as a backup in case of system cooling failure. Overall, the system

thermal design should allow the power delivery circuitry to operate within its temperature specification even while the processor is operating at its Processor Base Power.

NOTE

During PROCHOT demotion, the core frequency may be reduced below LFM for several uSec.

Thermal Solution Design and PROCHOT# Behavior 4.1.3.8

With a properly designed and characterized thermal solution, it is anticipated that PROCHOT# will only be asserted for very short periods of time when running the most power intensive applications. The processor performance impact due to these brief periods of TCC activation is expected to be so minor that it would be immeasurable. However, an under-designed thermal solution that is not able to prevent excessive assertion of PROCHOT# in the anticipated ambient environment may:

- Cause a noticeable performance loss.
- Result in prolonged operation at or above the specified maximum junction temperature and affect the long-term reliability of the processor.
- May be incapable of cooling the processor even when the TCC is active continuously (in extreme situations).

Low-Power States and PROCHOT# Behavior 4.1.3.9

Depending on package power levels during package C-states, outbound PROCHOT# may de-assert while the processor is idle as power is removed from the signal. Upon wake up, if the processor is still hot, the PROCHOT# will re-assert, although typically package idle state residency should resolve any thermal issues. The PECI interface is fully operational during all C-states and it is expected that the platform continues to manage processor IA core and package thermals even during idle states by regularly polling for thermal data over PECI.

THRMTRIP# Signal 4.1.3.10

Regardless of enabling the automatic or on-demand modes, in the event of a catastrophic cooling failure, the package will automatically shut down when the silicon has reached an elevated temperature that risks physical damage to the product. At this point, the THRMTRIP# signal will go active.

Critical Temperature Detection 4.1.3.11

Critical Temperature detection is performed by monitoring the package temperature. This feature is intended for graceful shutdown before the THRMTRIP# is activated. However, the processor execution is not guaranteed between critical temperature and THRMTRIP#. If the Adaptive Thermal Monitor is triggered and the temperature remains high, a critical temperature status and sticky bit are latched in the PACKAGE_THERM_STATUS (0x1B1) MSR and the condition also generates a thermal interrupt, if enabled.

On-Demand Mode 4.1.3.12

The processor provides an auxiliary mechanism that allows system software to force the processor to reduce its power consumption using clock modulation. This mechanism is referred to as "On-Demand" mode and is distinct from Adaptive Thermal Monitor and bi-directional PROCHOT#. The processor platforms should not rely on software usage of this mechanism to limit the processor temperature. On-Demand Mode can be accomplished using processor MSR or chipset I/O emulation. On-Demand Mode may be used in conjunction with the Adaptive Thermal Monitor. However, if the system software tries to enable On-Demand mode at the same time the TCC is engaged, the factory configured the duty cycle of the TCC will override the duty cycle selected by the On-Demand mode. If the I/O based and MSR-based On-Demand modes are in conflict, the duty cycle selected by the I/O emulation-based On-Demand mode will take precedence over the MSR-based On-Demand Mode.

MSR Based On-Demand Mode 4.1.3.13

If Bit 4 of the IA32_CLOCK_MODULATION MSR is set to 1, the processor will immediately reduce its power consumption using modulation of the internal processor IA core clock, independent of the processor temperature. The duty cycle of the clock modulation is programmable using bits [3:1] of the same IA32_CLOCK_MODULATION MSR. In this mode, the duty cycle can be programmed in either 12.5% or 6.25% increments (discoverable using CPUID). Thermal throttling using this method will modulate each processor IA core's clock independently.

I/O Emulation-Based On-Demand Mode 4.1.3.14

I/O emulation-based clock modulation provides legacy support for operating system software that initiates clock modulation through I/O writes to ACPI defined processor clock control registers on the chipset (PROC_CNT). Thermal throttling using this method will modulate all processor IA cores simultaneously.

Intel® Memory Thermal Management 4.1.4

DRAM Thermal Aggregation

P-Unit firmware is responsible for aggregating DRAM temperature sources into a per-DIMM reading as well as an aggregated virtual 'max' sensor reading. At reset, MRC communicates to the MC the valid channels and ranks as well as DRAM type. At that time, Punit firmware sets up a valid channel and rank mask that is then used in the thermal aggregation algorithm to produce a single maximum temperature

DRAM Thermal Monitoring

- DRAM thermal sensing Periodic DDR thermal reads from DDR
- DRAM thermal calculation Punit reads of DDR thermal information direct from the memory controller (MR4 or MPR) Punit estimation of a virtual maximum DRAM temperature based on per-rank readings. Application of thermal filter to the virtual maximum temperature.

DRAM Refresh Rate Control

The MRC will natively interface with MR4 or MPR readings to adjust DRAM refresh rate as needed to maintain data integrity. This capability is enabled by default and occurs automatically. Direct override of this capability is available for debug purposes, but this cannot be adjusted during runtime.

General Notes 4.2

System Memory Timing Support 5.1.3

The IMC supports the following DDR Speed Bin, CAS Write Latency (CWL), and command signal mode timings on the main memory interface:

- \bullet tCL = CAS Latency
- tRCD = Activate Command to READ or WRITE Command delay
- tRP = PRECHARGE Command Period
- tRPb = per-bank PRECHARGE time
- tRPab = all-bank PRECHARGE time
- CWL = CAS Write Latency
- Command Signal modes:
	- 2N indicates a new DDR5/DDR4/LPDDR4x/LPDDR5/x command may be issued every 2 clocks
	- 1N indicates a new DDR5/DDR4/LPDDR4x/LPDDR5/x command may be issued every clock.

System Memory Timing Support 5.1.3.1

Table 41. DDR System Memory Timing Support

| 1. 2 DPC supported when one slot is populated in each channel

Table 42. LPDDR System Memory Timing Support

SAGV Points 5.1.3.2

SAGV (System Agent Geyserville) is a way by which they SoC can dynamically scale the work point (V/F), by applying DVFS (Dynamic Voltage Frequency Scaling) based on memory bandwidth utilization and/or the latency requirement of the various workloads for better energy efficiency at System-Agent.heuristics are in charge of providing request for work points by periodically evaluating the utilization of the memory and IA stalls.

Table 43. SA Speed Enhanced Speed Steps (SA-GV) and Gear Mode Frequencies

- c. **HighBW** Characterized by high power, low latency, moderate BW also used as RFI mitigation point.
- d. **MaxBW/ lowest latency** Lowest Latency point, low BW and highest power.
- 3. Intel® System Agent Enhanced Speed Step® is not enabled for S/S Refresh-Processor 125W/150W SKUs
- 4. SAGV point may change based on memory module Type.
- 5. On mixed module type configurations, the selected SAGV point will be the set to the lower frequency configuration.

13th Generation Intel® Core™, Intel® Core™ 14th Generation, Intel® Core™ Processor (Series 1) and (Series 2), and Intel® Xeon™ E

DDR Frequency Shifting 5.1.3.3

DDR interfaces emit electromagnetic radiation which can couple to the antennas of various radios that are integrated in the system, and cause radio frequency interference (RFI).

The DDR Radio Frequency Interference Mitigation (DDR RFIM) feature is primarily aimed at resolving narrowband RFI from DDR4/5 and LPDDR4/5 technologies for the Wi-Fi* high and ultra-high bands (\sim 5-7 GHz).

By changing the DDR data rate, the harmonics of the clock can be shifted out of a radio band of interest, thus mitigating RFI to that radio. This feature is working with SAGV on, the 3rd SAGV point is used as RFI mitigation point.

Memory Controller (MC) 5.1.4

The integrated memory controller is responsible for transferring data between the processor and the DRAM as well as the DRAM maintenance. There are two instances of MC, one per memory slice. Each controller is capable of supporting up to four channels of LPDDR4x and LPDDR5, two channels of DDR5 and one channel of DDR4.

The two controllers are independent and have no means of communicating with each other, they need to be configured separately.

In a symmetric memory population, each controller only view half of the total physical memory address space.

Both MC support only one technology in a system, DDR4 or DDR5 or LPDDR4X, or LPDDR5. Mix of technologies in one system is not allowed.

Memory Controller Power Gate 5.1.5

Memory Controller Power Gating can only be done for MC0 which is connected to a separate power domain. MC0 will be gated automatically when it is not occupied.

NOTE

MC1 cannot be gated.

System Memory Controller Organization Mode (DDR4/5 Only) 5.1.6

The IMC supports two memory organization modes, single-channel and dual-channel. Depending upon how the DDR Schema and DIMM Modules are populated in each memory channel, a number of different configurations can exist.

Single-Channel Mode

In this mode, all memory cycles are directed to a single channel. Single-Channel mode is used when either the Channel A or Channel B DIMM connectors are populated in any order, but not both.

Dual-Channel Mode – Intel® Flex Memory Technology Mode

The IMC supports Intel Flex Memory Technology Mode. Memory is divided into a symmetric and asymmetric zone. The symmetric zone starts at the lowest address in each channel and is contiguous until the asymmetric zone begins or until the top

address of the channel with the smaller capacity is reached. In this mode, the system runs with one zone of dual-channel mode and one zone of single-channel mode, simultaneously, across the whole memory array.

NOTE

Channels A and B can be mapped for physical channel 0 and 1 respectively or vice versa; however, channel A size should be greater or equal to channel B size.

Figure 19. Intel® DDR4/5 Flex Memory Technology Operations

Dual-Channel Symmetric Mode (Interleaved Mode)

Dual-Channel Symmetric mode, also known as interleaved mode, provides maximum performance on real world applications. Addresses are ping-ponged between the channels after each cache line (64-byte boundary). If there are two requests, and the second request is to an address on the opposite channel from the first, that request can be sent before data from the first request has returned. If two consecutive cache lines are requested, both may be retrieved simultaneously, since they are ensured to be on opposite channels. Use Dual-Channel Symmetric mode when both Channel A and Channel B DIMM connectors are populated in any order, with the total amount of memory in each channel being the same.

When both channels are populated with the same memory capacity and the boundary between the dual channel zone and the single channel zone is the top of memory, IMC operates completely in Dual-Channel Symmetric mode.

NOTES

- The DRAM device technology and width may vary from one channel to another.
- Different memory size between channels are relevant to DDR4 and DDR5 only.

System Memory Frequency 5.1.7

In all modes, the frequency of system memory is the lowest frequency and latency of all memory modules placed in the system, as determined through the SPD registers on the memory modules. The system memory controller supports a single DIMM connector per channel. If DIMMs with different latency are populated across the channels, the BIOS will use the slower of the two latencies for both channels. For Dual-Channel modes, both channels should have a DIMM connector populated. For Single-Channel mode, only a single channel can have a DIMM connector populated.

Technology Enhancements of Intel® FMA 5.1.8

The following sections describe the Just-in-Time Scheduling, Command Overlap, and Out-of-Order Scheduling Intel® Fast Memory Access (Intel® FMA) technology enhancements.

Just-in-Time Command Scheduling

The memory controller has an advanced command scheduler where all pending requests are examined simultaneously to determine the most efficient request to be issued next. The most efficient request is picked from all pending requests and issued to system memory Just-in-Time to make optimal use of Command Overlapping. Thus, instead of having all memory access requests go individually through an arbitration mechanism forcing requests to be executed one at a time, they can be started without interfering with the current request allowing for concurrent issuing of requests. This allows for optimized bandwidth and reduced latency while maintaining appropriate command spacing to meet system memory protocol.

Command Overlap

Command Overlap allows the insertion of the DRAM commands between the Activate, Pre-charge, and Read/Write commands normally used, as long as the inserted commands do not affect the currently executing command. Multiple commands can be issued in an overlapping manner, increasing the efficiency of system memory protocol.

Out-of-Order Scheduling

While leveraging the Just-in-Time Scheduling and Command Overlap enhancements, the IMC continuously monitors pending requests to system memory for the best use of bandwidth and reduction of latency. If there are multiple requests to the same open page, these requests would be launched in a back to back manner to make optimum use of the open memory page. This ability to reorder requests on the fly allows the IMC to further reduce latency and increase bandwidth efficiency.

Data Scrambling 5.1.9

The system memory controller incorporates a Data Scrambling feature to minimize the impact of excessive di/dt on the platform system memory VRs due to successive 1s and 0s on the data bus. Past experience has demonstrated that traffic on the data bus is not random and can have energy concentrated at specific spectral harmonics creating high di/dt which is generally limited by data patterns that excite resonance between the package inductance and on die capacitances. As a result, the system memory controller uses a data scrambling feature to create pseudo-random patterns on the system memory data bus to reduce the impact of any excessive di/dt.

ECC H-Matrix Syndrome Codes 5.1.10

2. This table is relevant only for S-Processor ECC supported SKUs.

Data Swapping 5.1.11

By default, the processor supports on-board data swapping in two manners (for all segments and DRAM technologies):

- DQ swapping is allowed within each Byte for all DDR technologies.
- •
- LPDDR4x byte cannot be swizzled within their x16 sub-channel

13th Generation Intel® Core™, Intel® Core™ 14th Generation, Intel® Core™ Processor (Series 1) and (Series 2), and Intel® Xeon™ E 2400 Processor

- LPDDR4x x16 sub-channels can be swizzled within their x32 channel
- LPDDR4x x32 channels can be swizzled within their x64 MC
- LPDDR5/x x16 sub-channels can be swizzle within their x64 MC
- DDR4: Byte swapping is allowed within each x64 Channel.
- DDR5: Byte swapping is allowed within a channel in 16-bit group: [0,1] [2,3].
- ECC bits swap is allowed within ECC byte/nibble: DDR4 ECC[7..0] and DDR5 ECC[3..0].

LPDDR5/x Ascending and Descending 5.1.12

LPDDR5/x support Ascending / descending that swap CA and CS signals connectivity order.

NOTE

Ascending / descending can be performed in every x16 sub channel.

LPDDR4x CMD Mirroring 5.1.13

LPDDR4x support Mirroring that swap CA signals connectivity order.

NOTE

Mirroring can be performed in every x16 sub channel

DDR I/O Interleaving 5.1.14

NOTE

The processor supports I/O interleaving, which has the ability to swap DDR bytes for routing considerations. BIOS configures the I/O interleaving mode before DDR training. P-Processor line packages are optimized only for Non-Interleaving mode (NIL).

There are two supported modes:

- Interleave (IL)
- Non-Interleave (NIL)

The following table and figure describe the pin mapping between the IL and NIL modes.

Table 44. Interleave (IL) and Non-Interleave (NIL) Modes Pin Mapping

^R *Intel® Core™ and Xeon™ E 2400 Processors—Memory*

Figure 20. DDR4 Interleave (IL) and Non-Interleave (NIL) Modes Mapping

DRAM Clock Generation 5.1.15

Each support rank has a differential clock pair for DDR4/5. Each sub-channel has a differential clock pair for LPDDR4x. Each sub-channel has a (CK_P/N and WCK_P/N) differential clock pair for LPDDR5/x.

DRAM Reference Voltage Generation 5.1.16

Read Vref is generated by the memory controller in all technologies. Write Vref is generated by the DRAM in all technologies. Command Vref is generated by the DRAM in LPDDR4x/5 while the memory controller generates VrefCA per DIMM for DDR4. In all cases, it has small step sizes and is trained by MRC.

Data Swizzling 5.1.17

All Processor Lines does not have die-to-package DDR swizzling.

Error Correction With Standard RAM 5.1.18

In-Band error-correcting code (IBECC) correct single-bit memory errors in standard, non-ECC memory.

Supported only in Chrome systems.

Post Package Repair 5.1.19

PPR is supported according to Jedec Spec.

BIOS can identify a single Row failure per Bank in DRAM and perform Post Package Repair (PPR) to exchange failing Row with spare Row.

PPR can be supported only with DRAM that supports PPR according to Jedec spec.

Supported technologies : DDR4, DDR5, LPDDR4x and LPDDR5/x.

Refresh Management (RFM) 5.1.20

RFM is supported according to JEDEC spec.

LPDDR5/x: RFM feature is enabled.

DDR5: RFM feature is not yet enabled.

Integrated Memory Controller (IMC) Power Management 5.2

The main memory is power managed during normal operation and in low-power ACPI C-states.

Disabling Unused System Memory Outputs 5.2.1

Any system memory (SM) interface signal that goes to a memory in which it is not connected to any actual memory devices (such as SODIMM connector is unpopulated, or is single-sided) is tri-stated. The benefits of disabling unused SM signals are:

- Reduced power consumption.
- Reduced possible overshoot/undershoot signal quality issues seen by the processor I/O buffer receivers caused by reflections from potentially unterminated transmission lines.

When a given rank is not populated, the corresponding control signals (CLK_P/ CLK_N/CKE/ODT/CS) are not driven.

At reset, all rows should be assumed to be populated, until it can be proven that they are not populated. This is due to the fact that when CKE is tri-stated with a DRAMs present, the DRAMs are not ensured to maintain data integrity. CKE tri-state should be enabled by BIOS where appropriate, since at reset all rows should be assumed to be populated.

DRAM Power Management and Initialization 5.2.2

The processor implements extensive support for power management on the memory interface. Each channel drives 4 CKE pins, one per rank.

The CKE is one of the power-saving means. When CKE is off, the internal DDR clock is disabled and the DDR power is reduced. The power-saving differs according to the selected mode and the DDR type used. For more information, refer to the IDD table in the DDR specification.

The processor supports four different types of power-down modes in package C0 state. The different power-down modes can be enabled through configuring PM PDWN config register. The type of CKE power-down can be configured through PDWN_mode (bits 15:12) and the idle timer can be configured through PDWN idle counter (bits 11:0).

The different power-down modes supported are:

• **No power-down**: (CKE disable)

intel

- **Active Power-down (APD):** This mode is entered if there are open pages when de-asserting CKE. In this mode the open pages are retained. Power-saving in this mode is the lowest. Power consumption of DDR is defined by IDD3P. Exiting this mode is fined by tXP – a small number of cycles.
- **Pre-charged Power-down (PPD):** This mode is entered if all banks in DDR are pre-charged when de-asserting CKE. Power-saving in this mode is intermediate – better than APD. Power consumption is defined by IDD2P. Exiting this mode is defined by tXP. The difference from APD mode is that when waking-up, all pagebuffers are empty.)

*APD is default in P and U Processor line, otherwise it's "No Power down".

The CKE is determined per rank, whenever it is inactive. Each rank has an idle counter. The idle-counter starts counting as soon as the rank has no accesses, and if it expires, the rank may enter power-down while no new transactions to the rank arrive to queues. The idle-counter begins counting at the last incoming transaction arrival. It is important to understand that since the power-down decision is per rank, the IMC can find many opportunities to power down ranks, even while running memory intensive applications; the savings are significant (may be few Watts, according to DDR specification). This is significant when each channel is populated with more ranks.

Selection of power modes should be according to power-performance or a thermal trade-off of a given system:

- When trying to achieve maximum performance and power or thermal consideration is not an issue: use no power-down
- In a system which tries to minimize power-consumption, try using the deepest power-down mode possible
- In high-performance systems with dense packaging (that is, tricky thermal design) the power-down mode should be considered in order to reduce the heating and avoid DDR throttling caused by the heating.

The idle timer expiration count defines the $#$ of DCLKs that a rank is idle that causes entry to the selected power mode. As this timer is set to a shorter time the IMC will have more opportunities to put the DDR in power-down. There is no BIOS hook to set this register. Customers choosing to change the value of this register can do it by changing it in the BIOS. For experiments, this register can be modified in real time if BIOS does not lock the IMC registers.

Initialization Role of CKE 5.2.2.1

During power-up, CKE is the only input to the SDRAM that has its level recognized (other than the reset pin) once power is applied. It should be driven LOW by the DDR controller to make sure the SDRAM components float DQ and DQS during power-up. CKE signals remain LOW (while any reset is active) until the BIOS writes to a configuration register. Using this method, CKE is ensured to remain inactive for much longer than the specified 200 micro-seconds after power and clocks to SDRAM devices are stable. In LPDDR5/DDR5, there is no CKE pin and the power management roll is assumed by the CS signals.

Conditional Self-Refresh 5.2.2.2

During S0 idle state, system memory may be conditionally placed into self-refresh state when the processor is in package C3 or deeper power state. Refer to [Intel](#page-70-0)[®] [Rapid Memory Power Management \(Intel](#page-70-0)® RMPM) on page 71 for more details on conditional self-refresh with Intel HD Graphics enabled.

When entering the S3 - Suspend-to-RAM (STR) state or S0 conditional self-refresh, the processor IA core flushes pending cycles and then enters SDRAM ranks that are not used by the processor graphics into self-refresh. The CKE signals remain LOW so the SDRAM devices perform self-refresh.

The target behavior is to enter self-refresh for package C3 or deeper power states as long as there are no memory requests to service.

Dynamic Power-Down 5.2.2.3

Dynamic power-down of memory is employed during normal operation. Based on idle conditions, a given memory rank may be powered down. The IMC implements aggressive CKE control to dynamically put the DRAM devices in a power-down state.

The processor IA core controller can be configured to put the devices in active power down (CKE de-assertion with open pages) or pre-charge power-down (CKE deassertion with all pages closed). Pre-charge power-down provides greater power savings but has a bigger performance impact, since all pages will first be closed before putting the devices in power-down mode.

If dynamic power-down is enabled, all ranks are powered up before doing a refresh cycle and all ranks are powered down at the end of the refresh.

DRAM I/O Power Management 5.2.2.4

Unused signals should be disabled to save power and reduce electromagnetic interference. This includes all signals associated with an unused memory channel. Clocks, CKE, ODT, and CS signals are controlled per DIMM rank and will be powered down for unused ranks.

The I/O buffer for an unused signal should be tri-stated (output driver disabled), the input receiver (differential sense-amp) should be disabled. The input path should be gated to prevent spurious results due to noise on the unused signals (typically handled automatically when input receiver is disabled).

DDR Electrical Power Gating 5.2.3

The DDR I/O of the processor supports Electrical Power Gating (DDR-EPG) while the processor is at C3 or deeper power state.

In C3 or deeper power state, the processor internally gates VDDQ and VDD2 for the majority of the logic to reduce idle power while keeping all critical DDR pins such as CKE and VREF in the appropriate state.

In C7 or deeper power state, the processor internally gates VCCSA for all non-critical state to reduce idle power.

In S3 or C-state transitions, the DDR does not go through training mode and will restore the previous training information.

Power Training 5.2.4

BIOS MRC performing Power Training steps to reduce DDR I/O power while keeping reasonable operational margins still guaranteeing platform operation. The algorithms attempt to weaken ODT, driver strength and the related buffers parameters both on the MC and the DRAM side and find the best possible trade-off between the total I/O power and the operating margins using advanced mathematical models.

6.0 USB-C* Sub System

USB-C* is a cable and connector specification defined by USB-IF.

The USB-C sub-system supports USB3, USB4, DPoC (DisplayPort over Type-C) protocols. The USB-C sub-system can also support be configured as native DisplayPort or HDMI interfaces, for more information refer to [Display](#page-152-0) on page 153.

Thunderbolt™ 4 is a USB-C solution brand which requires the following elements:

- USB2, USB3 (10 Gbps), USB3/DP implemented at the connector.
- In additional, it requires USB4 implemented up to 40 Gbps, including Thunderbolt 3 compatibility as defined by USB4/USB-PD specs and 15 W of bus power
- Thunderbolt 4 solutions use (and prioritize) the USB4 PD entry mode (while still supporting Thunderbolt 3 alt mode)
- This product has the ability to support these requirements

NOTE

If USB4 (20 Gbps) only solutions are implemented, Thunderbolt 3 compatibility as defined by USB4/USB-PD specs and 15 W of bus power are still recommended

General Capabilities 6.1

- xHCI (USB 3 host controller) and xDCI (USB 3 device controller) implemented in the processor in addition to the controllers in the PCH.
- No support for USB Type-A on the processor side, For USB Type-A implementation and capabilities refer to PCH Datasheet Vol1.
- Intel AMT/vPro over Thunderbolt docking.
- Support power saving when USB-C* disconnected.
- Support up to four simultaneous ports.
- DbC Enhancement for Low Power Debug until Pkg C6
- Host
	- Aggregate BW through the controller at least 3 GB/s, direct connection or over USB4.
	- Wake capable on each host port from S0i3, Sx: Wake on Connects, Disconnects, Device Wake.
- **Device**
	- Aggregate BW through xHCI controller of at least 3 GB/s
	- D0i2 and D0i3 power gating
	- Wake capable on host initiated wakes when the system is in S0i3, Sx Available on all ports

- Port Routing Control for Dual Role Capability
	- Needs to support SW/FW and ID pin based control to detect host versus device attach
	- SW mode requires PD controller or other FW to control
- USB-R device to host controller connection is over UTMI+ links.

Table 45. USB-C* Port Configuration

- a. USB4 Gen 2x2 (20 Gbps)
- b. USB4 Gen 3x2 (40 Gbps)
- c. 10.3125 Gbps, 20.625 Gbps Compatible to Thunderbolt 3 non-rounded modes.
- 5. USB 2 interface supported over Type-C connector, sourced from PCH.
- 6. Port group is defined as two ports sharing the same USB4 router, each router supports up to two display interfaces.
- 7. Display interface can be connected directly to a DP/HDMI/Type-C port or thru USB4 router on a Type-C connector.
- 8. If two ports in the same group are configured to one as USB4 and the other as DP/HDMI fixed connection each port will support single display interface.

Table 46. USB-C* Port Configuration

8. If two ports in the same group are configured to one as USB4 and the other as DP/HDMI fixed connection each port will support single display interface.

Table 47. USB-C* Lanes Configuration

Table 48. USB-C* Non-Supported Lane Configuration

USB* 4 Router 6.2

USB4 is a Standard architecture (formerly known as CIO), but with the addition of USB3 (10G) tunneling, and rounded frequencies. USB4 adds a new USB4 PD entry mode, but fully documents mode entry, and negotiation elements of Thunderbolt™ 3.

USB4 architecture (formerly known as Thunderbolt 3 protocol) is a transformational high-speed, dual protocol I/O, and it provides flexibility and simplicity by encapsulating both data (PCIe* & USB3) and video

(DisplayPort*) on a single cable connection that can daisy-chain up to six devices. USB4/Thunderbolt controllers act as a point of entry or a point of exit in the USB4 domain. The USB4 domain is built as a daisy chain of USB4/Thunderbolt enabled products for the encapsulated protocols - PCIe, USB3 and DisplayPort. These protocols are encapsulated into the USB4 fabric and can be tunneled across the domain.

USB4 controllers can be implemented in various systems such as PCs, laptops and tablets, or devices such as storage, docks, displays, home entertainment, cameras, computer peripherals, high end video editing systems, and any other PCIe based device that can be used to extend system capabilities outside of the system's box.

The integrated connection maximum data rate is 20.625 Gbps per lane but supports also 20.0 Gbps, 10.3125 Gbps, and 10.0 Gbps and is compatible with older Thunderbolt™ device speeds.

USB 4 Host Router Implementation Capabilities 6.2.1

The integrated USB-C sub-system implements the following interfaces via USB 4:

- Up to two DisplayPort* sink interfaces each one capable of:
	- DisplayPort 1.4 specification for tunneling
	- 1.62 Gbps or 2.7 Gbps or 5.4 Gbps or 8.1 Gbps link rates
	- $x1$, x2 or x4 lane operation
	- Support for DSC compression
- Up to two PCI Express* Root Port interfaces each one capable of:
	- PCI Express* 3.0 x4 compliant @ 8.0 GT/s
- Up to two xHCI Port interfaces each one capable of:
	- USB 3.2 Gen2x1 (10 Gbps)
- USB 4 Host Interface:
	- PCI Express* 3.0 x4 compliant endpoint
	- Supports simultaneous transmit and receive on 12 paths
	- Raw mode and frame mode operation configurable on a per-path basis
	- MSI and MSI-X support
	- Interrupt moderation support
- USB 4 Time Management Unit (TMU):
- Up to two Interfaces to USB-C* connectors, each one supports:
	- USB4 PD entry mode, as well as TBT 3 compatibility mode, each supporting:
		- 20 paths per port
		- Each port support 20.625/20.0 Gbps or 10.3125/10.0 Gbps link rates.
		- 16 counters per port

USB-C Sub-system xHCI/xDCI Controllers 6.3

The processor supports xHCI/xDCI controllers. The native USB 3 path proceeds from the memory directly to PHY.

USB 3 Controllers 6.3.1

Extensible Host Controller Interface (xHCI)

Extensible Host Controller Interface (xHCI) is an interface specification that defines Host Controller for a universal Serial Bus (USB 3), which is capable of interfacing with USB 1.x, 2.0, and 3.x compatible devices.

In case that a device (example, USB3 mouse) was connected to the computer, the computer will work as Host and the xHCI will be activated inside the CPU.

The xHCI controller support link rate of up to USB 3.2 Gen 2x2 (2x10G).

Extensible Device Controller Interface (xDCI)

Extensible Device Controller Interface (xDCI) is an interface specification that defines Device Controller for a universal Serial Bus (USB 3), which is capable of interfacing with USB 1.x, 2.0, and 3.x compatible devices.

In case that the computer is connected as a device (example, tablet connected to desktop) to another computer then the xDCI controller will be activated inside the device and will talk to the Host at the other computer.

The xDCI controller support link rate of up to USB 3.2 Gen 1x1 (5G).

NOTE

These controllers are instantiated in the processor die as a separate PCI function functionality for the USB-C* capable ports.

USB-C Sub-System PCIe Interface 6.3.2

Table 49. PCIe via USB4 Configuration

Table 50. PCIe via USB4 Configuration

USB-C Sub-System Display Interface 6.4

Refer [Display](#page-152-0) on page 153.

7.0 PCIe* Interface

This chapter provides information on the PCIe* Interface.

Processor PCI Express* Interface 7.1

This section describes the PCI Express* interface capabilities of the processor. Refer to *PCI Express Base* Specification 5.0* for details on PCI Express*.

NOTE

PCIe Gen 5.0 is not supported on P/PX/U Processor Lines. The below applies for PCIe Gen4.0 and lower

PCI Express* Support 7.1.1

The S/S Refresh/E processor PCI Express* has two interfaces:

- 16-lane (x16) port supporting PCIE to gen 5.0 or below that can also be configured as multiple ports at narrower widths.
- 4-lane (x4) port supporting PCIE gen 4.0 or below.

The HX/HX Refresh processor line PCI Express* has two interfaces:

- 16-lane (x16) port supporting PCIE to gen 5.0 or below that can also be configured as multiple ports at narrower widths.
- 4-lane (x4) port supporting PCIE gen 4.0 or below.

The H/H Refresh processor line PCI Express* has three interfaces:

- One 8-lane (x8) port supporting PCIE to gen 5.0 or below. This interface is available on certain SKU
- Two 4-lane (x4) port supporting PCIE gen 4.0 or below.

The PX processor line PCI Express* has two interfaces:

- One 8-lane (x8) port supporting PCIE to gen 4.0 or below. This interface is available on certain SKU
- One 4-lane (x4) port supporting PCIE gen 4.0 or below.

The P processor line PCI Express* has two interfaces:

• Two 4-lane (x4) port supporting PCIE gen 4.0 or below.

The U/U Refresh processor line PCI Express* has two interfaces:

• Two 4-lane (x4) port supporting PCIE gen 4.0 or below.

The processor supports the following:

13th Generation Intel® Core™, Intel® Core™ 14th Generation, Intel® Core™ Processor (Series 1) and (Series 2), and Intel® Xeon™ E

2400 Processor

1. Byte order ECN not supported

2. 4096 GB limit (Bits 63:43 always zeros)

3. Processor responds to upstream read transactions to addresses above 4096 GB (addresses where any of Bits 63:43 are non-zero) with an Unsupported Request response. Upstream write transactions to addresses above 4096 GB will be dropped 4. SRIS is enabled in PCH PCIe RP and not in CPU PCIe RP

5. Only MSI is supported, MSI-X is not supported (no need for many vector)

6. U/U Refresh dGPU is supported but not validated

- Hierarchical PCI-compliant configuration mechanism for downstream devices.
- Traditional PCI style traffic (asynchronous snooped, PCI ordering).
- PCI Express* extended configuration space. The first 256 bytes of configuration space aliases directly to the PCI Compatibility configuration space. The remaining portion of the fixed 4-KB block of memory-mapped space above that (starting at 100h) is known as extended configuration space.
- PCI Express* Enhanced Access Mechanism. Accessing the device configuration space in a flat memory-mapped fashion.
- Automatic discovery, negotiation, and training of link out of reset.
- Multiple Virtual Channel for Gen 4 port only*.
- 64-bit downstream address format, but the processor never generates an address above 4096 GB (Bits 63:43 will always be zeros).
- 64-bit upstream address format, but the processor responds to upstream read transactions to addresses above 4096 GB (addresses where any of Bits 63:43 are nonzero) with an Unsupported Request response. Upstream write transactions to addresses above 4096 GB will be dropped.
- Re-issues Configuration cycles that have been previously completed with the Configuration Retry status.
- PCI Express* reference clock is a 100-MHz differential clock.
- Power Management Event (PME) functions.
- Modern standby
- Dynamic width capability.
- Message Signaled Interrupt (MSI and MSI-X) messages.
- Lane reversal
- Advanced Error Reporting (AER)
- MCTP VDM tunneling.
- ACS Access control services
- Precision Time Measurement (PTM) This feature is supported on PEG60/62 with the exception of ECN for byte ordering of the PTM value not being supported. PEG10/11 do support ECN for byte ordering

The S/S Refresh/E/HX/HX Refresh processor supports the configurations shown in the following tables:

Table 51. PCI Express* 16 - Lane Bifurcation and Lane Reversal Mapping

b. Connect lane 0 of 2nd device to lane 8.

4. For reversal lanes, for example: When using 1x8, the 8 lane device should use lanes 8:15, so lane 15 will be connected to lane 0 of the Device.

Table 52. S/S Refresh/E/HX/HX Refresh - Processor PCI Express* 4 - Lane Reversal Mapping

The H/H Refresh/PX processor lines supports the configurations shown in the following tables:

^R *Intel® Core™ and Xeon™ E 2400 Processors—PCIe* Interface*

Table 53. H/H Refresh/PX PCI Express* 8 - Lane Reversal Mapping

3. For reversal lanes, for example: When using 1x4, the 4 lane device should use lanes 4:7, so lane 7 will be connected to lane 0 of the Device.

The H/H Refresh/PX/P/U/U Refresh processor Lines supports the configurations shown in the following tables:

Table 54. H/H Refresh/PX/P/U/U Refresh PCI Express* 4 - Lane Reversal Mapping

Table 55. PCI Express* Maximum Transfer Rates and Theoretical Bandwidth

The above table summarizes the transfer rates and theoretical bandwidth of PCI Express* link.

PCI Express* Architecture 7.1.2

Compatibility with the PCI addressing model is maintained to ensure that all existing applications and drivers operate unchanged.

The PCI Express* configuration uses standard mechanisms as defined in the PCI Plugand-Play specification.

The processor PCI Express* port supports Gen 4 at 16GT/s uses a 128b/130b encoding and Gen 5 at 32 GT/s uses a 128b/130b encoding

S/HX/S Refresh/HX Refresh/E-Processor Line: The 4 lanes port can operate at 2.5 GT/s, 5 GT/s, 8 GT/s or 16 GT/s.

S/HX/S Refresh/HX Refresh/E-Processor Line: The 16 lanes port can operate at 2.5 GT/s, 5 GT/s, 8 GT/s, 16 GT/s or 32 GT/s**

H/H Refresh/P/PX/U/U Refresh -Processor Line: Each of the 4 lanes ports can operate at 2.5 GT/s, 5 GT/s, 8 GT/s or 16 GT/s.

H/H Refresh-Processor Line: The 8 lane port can operate at 2.5 GT/s, 5 GT/s, 8 GT/s, 16 GT/s or 32 GT/s**

PX-Processor Line: The 8 lane port can operate at 2.5 GT/s, 5 GT/s, 8 GT/s, or 16 GT/s**

The PCI Express* architecture is specified in three layers – Transaction Layer, Data Link Layer, and Physical Layer. Refer to the PCI Express Base Specification 5.0 for details of PCI Express* architecture.

PCI Express* Configuration Mechanism 7.1.3

The PCI Express* (external graphics) link is mapped through a PCI-to-PCI bridge structure.

Figure 21. PCI Express* Related Register Structures in the Processor

13th Generation Intel® Core™, Intel® Core™ 14th Generation, Intel® Core™ Processor (Series 1) and (Series 2), and Intel® Xeon™ E 2400 Processor December 2024 Datasheet, Volume 1 of 2 The PCI Express* Host Bridge is required to translate the memory-mapped PCI Express* configuration space accesses from the host processor to PCI Express* configuration cycles. To maintain compatibility with PCI configuration addressing mechanisms, it is recommended that system software access the enhanced configuration space using 32-bit operations (32-bit aligned) only. Refer to the PCI Express Base Specification for details of both the PCI-compatible and PCI Express* Enhanced configuration mechanisms and transaction rules.

PCI Express* Equalization Methodology 7.1.4

Link equalization requires equalization for both TX and RX sides for the processor and for the Endpoint device.

Adjusting transmitter and receiver of the lanes is done to improve signal reception quality and for improving link robustness and electrical margin.

The link timing margins and voltage margins are strongly dependent on equalization of the link.

The processor supports the following:

- **Full TX Equalization**: Three Taps Linear Equalization (Pre, Current and Post cursors), with FS/LF (Full Swing /Low Frequency) values.
- Full RX Equalization and acquisition for AGC (Adaptive Gain Control), CDR (Clock and Data Recovery), adaptive DFE (decision feedback equalizer) and adaptive CTLE peaking (continuous time linear equalizer).
- Full adaptive phase 3 EQ compliant with PCI Express* Gen 3 and Gen 4 specification.

PCI Express* Hot Plug 7.1.5

PCI Express Hot Plug not supported.

8.0 Direct Media Interface and On Package Interface

Direct Media Interface (DMI) 8.1

NOTE

The DMI interface is only present in 2-Chip platform processors.

Direct Media Interface (DMI) connects the processor and the PCH.

The main characteristics are as follows:

- 8 lanes Gen 4 DMI support
- 4 lanes Gen 4 Reduced DMI support
- 16 GT/s point-to-point DMI interface to PCH
- DC coupling no capacitors between the processor and the PCH
- PCH end-to-end lane reversal across the link
- L0 (Active) and L1 (Low power) states support
- Half-Swing support (low-power/low-voltage)

DMI Error Flow 8.1.1

DMI can only generate SERR in response to errors; never SCI, SMI, MSI, PCI INT, or GPE. Any DMI related SERR activity is associated with Device 0.

DMI Link Down 8.1.2

The DMI link going down is a fatal, unrecoverable error. If the DMI data link goes to data link down, after the link was up, then the DMI link hangs the system by not allowing the link to retrain to prevent data corruption. This link behavior is controlled by the PCH.

Downstream transactions that had been successfully transmitted across the link prior to the link going down may be processed as normal. No completions from downstream, non-posted transactions are returned upstream over the DMI link after a link down event.

On Package Interface (OPI) 8.2

OPI Support 8.2.1

The processor communicates with the PCIe using an internal interconnect BUS named OPI.

Functional Description 8.2.2

OPI operates at 4 GT/s bus rate.

9.0 Graphics

Processor Graphics 9.1

The processor graphics is based on X^e graphics core architecture that enables substantial gains in performance and lower-power consumption over prior generations. X^e architecture supports up to 96 Execution Units (EUs) depending on the processor SKU.

The processor graphics architecture delivers high dynamic range of scaling to address segments spanning low power to high power, increased performance per watt, support for next generation of APIs. X^e scalable architecture is partitioned by usage domains along Render/Geometry, Media, and Display. The architecture also delivers very lowpower video playback and next generation analytics and filters for imaging related applications. The new Graphics Architecture includes 3D compute elements, Multiformat HW assisted decode/encode pipeline, and Mid-Level Cache (MLC) for superior high definition playback, video quality, and improved 3D performance and media.

Media Support (Intel® QuickSync and Clear Video Technology HD) 9.1.1

 X^e implements multiple media video codecs in hardware as well as a rich set of image processing algorithms.

NOTE

HEVC and VP9 support additional 10bpc, YCbCr 4:2:2 or 4:4:4 profiles. Refer additional detail support matrix.

Hardware Accelerated Video Decode 9.1.1.1

 X^e implements a high-performance and low-power HW acceleration for video decoding operations for multiple video codecs.

The HW decode is exposed by the graphics driver using the following APIs:

- Direct3D* 9 Video API (DXVA2)
- Direct3D11 Video API
- Direct3D12 Video API
- Intel Media SDK
- MFT (Media Foundation Transform) filters.
- Intel VA API

Xe supports full HW accelerated video decoding for AVC/HEVC/VP9/JPEG/AV1.

intel

Table 56. Hardware Accelerated Video Decoding

NOTE

Video playback best performance can be achieved by enabling display MPO with minimized EU workloads. In some test scenarios, it may act differently.

For example, 8k playback on less than 8k monitors, in non-full screen mode or some UI operations and unexpected end user behaviors etc. - These will hit MPO limitation or simply applications do not use MPO.

Then graphics driver need to use EU for rendering/composition, and 8K E2E playback has dependency on EU counts capability.

Expected performance: More than 16 simultaneous decode streams @ 1080p.

NOTE

Actual performance depends on the processor SKU, content bit rate, and memory frequency. Hardware decode for H264 SVC is not supported.

Hardware Accelerated Video Encode 9.1.1.2

Gen12 implements a low-power low-latency fixed function encoder and a high-quality customizable encoder with hardware assisted motion estimation engine which supports AVC, MPEG-2, HEVC, and VP9.

The HW encode is exposed by the graphics driver using the following APIs:

- Intel® Media SDK
- MFT (Media Foundation Transform) filters

Xe supports full HW accelerated video encoding for AVC/HEVC/VP9/JPEG.

Table 57. Hardware Accelerated Video Encode

NOTE

Hardware encode for H264 SVC is not supported.

Hardware Accelerated Video Processing 9.1.1.3

There is hardware support for image processing functions such as De-interlacing, Film cadence detection, Advanced Video Scaler (AVS), detail enhancement, gamut compression, HD adaptive contrast enhancement, skin tone enhancement, total color control, Chroma de-noise, SFC (Scalar and Format Conversion), memory compression, Localized Adaptive Contrast Enhancement (LACE), spatial de-noise, Out-Of-Loop Deblocking (from AVC decoder), 16 bpc support for de-noise/de-mosaic.

The HW video processing is exposed by the graphics driver using the following APIs:

- Direct3D* 9 Video API (DXVA2).
- Direct3D* 11 Video API.
- OneVPL
- MFT (Media Foundation Transform) filters.
- Intel[®] Graphics Control Library
- Intel VA API

NOTE

Not all features are supported by all the above APIs. Refer to the relevant documentation for more details.

Hardware Accelerated Transcoding 9.1.1.4

Transcoding is a combination of decode, video processing (optional) and encode. Using the above hardware capabilities can accomplish a high-performance transcode pipeline. There is not a dedicated API for transcoding.

The processor graphics supports the following transcoding features:

- High performance high quality flexible encoder for video editing, video archiving.
- Low-power low latency encoder for video conferencing, wireless display, and game streaming.
- Lossless memory compression for media engine to reduce media power.
- High-quality Advanced Video Scaler (AVS)
- Low power Scaler and Format Converter.

Platform Graphics Hardware Feature 9.1.2

Hybrid Graphics 9.1.2.1

Microsoft* Windows* operating system enables the Windows* Hybrid graphics framework wherein the GPUs and their drivers can be simultaneously utilized to provide users with the benefits of both performance capability of discrete GPU (dGPU) and low-power display capability of the processor GPU (iGPU). For instance, when there is a high-end 3D gaming workload in progress, the dGPU will process and render the game frames using its graphics performance, while iGPU continues to perform the display operations by compositing the frames rendered by dGPU. We recommend that OEMS should seek further guidance from Microsoft* to confirm that the design fits all the latest criteria defined by Microsoft* to support HG.

Microsoft* Hybrid Graphics definition includes the following:

- 1. The system contains a single integrated GPU and a single discrete GPU.
- 2. It is a design assumption that the discrete GPU has a significantly higher performance than the integrated GPU.
- 3. Both GPUs shall be physically enclosed as part of the system.
	- a. Microsoft* Hybrid DOES NOT support hot-plugging of GPUs
	- b. OEMS should seek further guidance from Microsoft* before designing systems with the concept of hot-plugging
- 4. Starting with Windows*10 Th1 (WDDM 2.0), a previous restriction that the discrete GPU is a render-only device, with no displays connected to it, has been removed. A render-only configuration with NO outputs is still allowed, just NOT required.

10.0 Display

Display Technologies Support 10.1

Display Configuration 10.2

Table 58. Display Ports Availability and Link Rate for P, H, U - Processor Lines

6. For non Type-C ports DisplayPort maximum supported link rate is HBR3.

Table 59. Display Ports Availability and Link Rate for PX - Processor Lines

3. HBR2 - 5.4 Gbps lane rate.

4. UHBR20 - 20 Gbps lane rate.

5. For non Type-C ports DisplayPort maximum supported link rate is HBR3.

Figure 23. P, PX/U/U Refresh/H/H Refresh Processor Display Architecture

NOTE

For port availability in each of the processor lines, refer to the above table.

Display Features 10.3

General Capabilities 10.3.1

- Up to four simultaneous displays.
	- Single 8K60Hz panel, supported by joining two pipes over single port.
	- Up to 4x4K60Hz display concurrent.
- Display interfaces supported:
	- DDI interfaces supports DP*, HDMI*, eDP*, DSI*
	- TCP interfaces supports DP*, HDMI*, Display Alt Mode over Type-C and Display tunneled.
	- Up to two wireless display captures.
- Audio stream support on external ports.
- HDR (High Dynamic Range) support.
- Four Display Pipes Supporting blending, color adjustments, scaling and dithering.
- Transcoders Containing the Timing generators supporting eDP*, DP*, HDMI* interfaces.
- Up to two Low Power optimized pipes supporting Embedded DisplayPort* and/or MIPI* DSI.
	- LACE (Localized Adaptive Contrast Enhancement), supported up to 5 K resolutions.
	- 3D LUT power efficient pixel modification function for color processing.
	- FBC (Frame Buffer Compression) power saving feature.

Multiple Display Configurations 10.3.2

The following multiple display configuration modes are supported (with appropriate driver software):

- Single Display is a mode with one display port activated to display the output to one display device.
- Display Clone is a mode with up to four display ports activated to drive the display content of same color depth setting but potentially different refresh rate and resolution settings to all the active display devices connected.
- Extended Desktop is a mode with up to four display ports activated to drive the content with potentially different color depth, refresh rate, and resolution settings on each of the active display devices connected.

High-bandwidth Digital Content Protection (HDCP) 10.3.3

HDCP is the technology for protecting high-definition content against unauthorized copy or unreceptive between a source (computer, digital set top boxes, and so on) and the sink (panels, monitor, and TVs). The processor supports both HDCP 2.3 and 1.4 content protection over wired displays (HDMI* and DisplayPort*).

The HDCP 1.4, 2.3 keys are integrated into the processor.

intel

DisplayPort* 10.3.4

The DisplayPort* is a digital communication interface that uses differential signaling to achieve a high-bandwidth bus interface designed to support connections between PCs and monitors, projectors, and TV displays.

A DisplayPort* consists of a Main Link (four lanes), Auxiliary channel, and a Hot-Plug Detect signal. The Main Link is a unidirectional, high-bandwidth, and low-latency channel used for transport of isochronous data streams such as uncompressed video and audio. The Auxiliary Channel (AUX CH) is a half-duplex bi-directional channel used for link management and device control. The Hot-Plug Detect (HPD) signal serves as an interrupt request from the sink device to the source device.

The processor is designed in accordance with VESA* DisplayPort* specification. Refer to [Display Technologies Support](#page-152-0) on page 153.

Figure 24. DisplayPort* Overview

- Support main link of 1, 2, or 4 data lanes.
- Link rate support up to UHBR20 (UHBR13.5 is not supported).
- Aux channel for Link/Device management.
- Hot Plug Detect.
- Support up to 36 BPP (Bit Per Pixel).
- Support SSC.
- Support YCbCR 4:4:4, YCbCR 4:2:0, YCbCR 4:2:2, and RGB color format.
- Support MST (Multi-Stream Transport).
- Support VESA DSC 1.1.
- Adaptive Sync.

Multi-Stream Transport (MST) 10.3.4.1

- The processor supports Multi-Stream Transport (MST), enabling multiple monitors to be used via a single DisplayPort connector.
- Maximum MST DP supported resolution:

Table 61. Display Resolutions and Link Bandwidth for Multi-Stream Transport Calculations

Notes: 1. All the above is related to bit depth of 24.

- 2. The data rate for a given video mode can be calculated as- Data Rate = Pixel Frequency * Bit Depth.
- 3. The bandwidth requirements for a given video mode can be calculated as: Bandwidth = Data Rate * 1.25 (for 8b/10b coding overhead).
- 4. The link bandwidth depends if the standards is reduced blanking or not. If the standard is not reduced blanking - the expected bandwidth may be higher. For more details, refer to VESA and Industry Standards and Guidelines for Computer Display Monitor Timing (DMT). Version 1.0, Rev. 13 February 8, 2013
- 5. To calculate what are the resolutions that can be supported in MST configurations, follow the below guidelines:
	- a. Identify what is the link bandwidth column according to the requested display resolution.
	- b. Summarize the bandwidth for two of three displays accordingly, and make sure the final result is below 21.6 Gbps. (for example: 4 lanes HBR2 bit rate)
	- For example:
	- a. Docking two displays: $3840x2160@60$ Hz + $1920x1200@60$ hz = $16 + 4.62$ = 20.62 Gbps [Supported]
	- b. Docking three displays: 3840x2160@30 Hz + 3840x2160@30 Hz + 1920x1080@60 Hz = $7.88 + 7.88 + 4.16 = 19.92$ Gbps [Supported].

Table 62. DisplayPort Maximum Resolution

intel

3. Resolution support is subject to memory BW availability.

4. Resolutions may consume two display pipes.

olution is based on the implementation of 4 lan

2. bpp - bit per pixel.

3. Resolution support is subject to memory BW availability.

4. Resolutions may consume two display pipes.

High-Definition Multimedia Interface (HDMI*) 10.3.5

The High-Definition Multimedia Interface (HDMI*) is provided for transmitting uncompressed digital audio and video signals from DVD players, set-top boxes, and other audio-visual sources to television sets, projectors, and other video displays. It can carry high-quality multi-channel audio data and all standard and high-definition consumer electronics video formats. The HDMI display interface connecting the processor and display devices uses transition minimized differential signaling (TMDS) to carry audiovisual information through the same HDMI cable.

HDMI* includes three separate communications channels: TMDS, DDC, and the optional CEC (consumer electronics control). CEC is not supported on the processor. As shown in the following figure, the HDMI* cable carries four differential pairs that make up the TMDS data and clock channels. These channels are used to carry video, audio, and auxiliary data. In addition, HDMI carries a VESA DDC. The DDC is used by an HDMI* Source to determine the capabilities and characteristics of the Sink.

Audio, video, and auxiliary (control/status) data is transmitted across the three TMDS data channels. The video pixel clock is transmitted on the TMDS clock channel and is used by the receiver for data recovery on the three data channels. The digital display data signals driven natively through the PCH are AC coupled and needs level shifting to convert the AC coupled signals to the HDMI* compliant digital signals. The processor HDMI* interface is designed in accordance with the High-Definition Multimedia Interface.

Figure 25. HDMI* Overview

- DDC (Display Data Channel) channel.
- Support YCbCR 4:4:4, YCbCR 4:2:0, YCbCR 4:2:2, and RGB color format.
- Support up to 36 BPP (Bit Per Pixel).
- Hot Plug Detect.

Table 63. HDMI Maximum Resolution

Notes: 1. bpp - bit per pixel.

2. Resolution support is subject to memory BW availability.

3. HDMI2.1 can be supported using PCON (DP1.4 to HDMI2.1 protocol converter).

2. Resolution support is subject to memory BW availability.

3. HDMI2.1 can be supported using PCON (DP1.4 to HDMI2.1 protocol converter).

^R *Intel® Core™ and Xeon™ E 2400 Processors—Display*

embedded DisplayPort* (eDP*) 10.3.6

The embedded DisplayPort* (eDP*) is an embedded version of the DisplayPort standard oriented towards applications such as notebook and All-In-One PCs. Like DisplayPort, embedded DisplayPort* also consists of the Main Link, Auxiliary channel, and an optional Hot-Plug Detect signal.

- Supported on Low power optimized pipes.
- Support up to HBR3 link rate.
- Support Backlight PWM control and enable signals, and power enable.
- Support VESA DSC 1.1.
- Support SSC.
- Panel Self Refresh 1.
- Panel Self Refresh 2
- MSO 2x2 (Multi Segment Operation).
- Adaptive Sync.

Table 64. Embedded DisplayPort Maximum Resolution

Notes: 1. Maximum resolution is based on the implementation of 4 lanes at HBR3 link data rate.

- 2. PSR2 supported for P and M processor lines only and up to 5 K resolutions.
- 3. bpp bit per pixel.
- 4. Resolution support is subject to memory BW availability.
- 5. High resolution panels supporting Display Stream Compression (DSC) are supported, technology enablement may be limited due to low market availability.

Notes: 1. Maximum resolution is based on the implementation of 4 lanes at HBR3 link data rate.

- 2. bpp bit per pixel.
- 3. Resolution support is subject to memory BW availability.
- 4. High resolution panels supporting Display Stream Compression (DSC) are supported,
- technology enablement may be limited due to low market availability.

MIPI* DSI 10.3.7

Display Serial Interface (DSI*) specifies the interface between a host processor and peripherals such as a display module. DSI is a high speed and high performance serial interface that offers efficient and low power connectivity between the processor and the display module.

- One link x8 data lanes or two links each with x4 lanes support.
- Supported on Low power optimized pipes.

- Support Backlight PWM control and enable signals, and power enable.
- Support VESA DSC (Data Stream Compression).

Figure 26. MIPI* DSI Overview

Table 65. MIPI* DSI Maximum Resolution

2. bpp - bit per pixel.

3. Resolution support is subject to memory BW availability.

Integrated Audio 10.3.8

- HDMI* and DisplayPort interfaces can carry audio along with video.
- The processor supports three High Definition audio streams on four digital ports simultaneously (the DMA controllers are in PCH).
- The integrated audio processing (DSP) is performed by the PCH and delivered to the processor using the AUDIO_SDI and AUDIO_CLK inputs pins.
- The AUDIO_SDO output pin is used to carry responses back to the PCH.
- Supports only the internal HDMI and DP CODECs.

^R *Intel® Core™ and Xeon™ E 2400 Processors—Display*

Table 66. Processor Supported Audio Formats over HDMI* and DisplayPort*

The processor will continue to support Silent stream. A Silent stream is an integrated audio feature that enables short audio streams, such as system events to be heard over the HDMI* and DisplayPort* monitors. The processor supports silent streams over the HDMI and DisplayPort interfaces at 44.1 kHz, 48 kHz, 88.2 kHz, 96 kHz, 176.4 kHz, and 192 kHz sampling rates and silent multi-stream support.

11.0 Camera/MIPI

Camera/MIPI is supported on the following processor line.

- P/PX-Processor line
- H/H Refresh-Processor line
- U/U Refresh -Processor line

NOTE

The availability of the features above may vary between different processor SKUs.

Camera Pipe Support 11.1

The IPU6se fixed function pipe supports the following functions:

- Black level correction;
- White balance;
- Color matching;
- Lens shading (vignette) correction;
- Color crosstalk (color shading) correction;
- Dynamic defect pixel replacement;
- Auto-focus-pixel (PDAF) hiding;
- High quality demosaic;
- Scaling and format conversion;
- Temporal noise reduction running on Intel graphics.

MIPI* CSI-2 Camera Interconnect 11.2

The Camera I/O Controller provides a native/integrated interconnect to camera sensors, compliant with MIPI* CSI-2 V2.0 protocol. Total of 8 data+4 clock lanes are available for the camera interface supporting up to 4 sensors .

Data transmission interface (referred as CSI-2) is a unidirectional differential serial interface with data and clock signals; the physical layer of this interface is the MIPI $*$ Alliance Specification for D-PHY.

The control interface (referred as CCI) is a bi-directional control interface compatible with I^2C standard.

Camera Control Logic 11.2.1

The camera infrastructure supports several architectural options for camera control utilizing camera PMIC and/or discrete logic. IPU6 control options utilize I²C for bidirectional communication and PCH GPIOs to drive various control functions.

Camera Modules 11.2.2

Intel maintains an Intel User Facing Camera Approved Vendor List and Intel World-Facing Approved Vendor List to simplify system design. Additional services are available to support non-AVL options.

Testability and Monitoring Signals 12.9

Error and Thermal Protection Signals 12.10

Table 73. Error and Thermal Protection Signals

Processor Power Rails 12.11

Table 74. Processor Power Rails Signals

Table 75. Processor Ground Rails Signals

Ground and Reserved Signals 12.12

The following are the general types of reserved (RSVD) signals and connection guidelines:

- RSVD these signals should not be connected
- RSVD TP these signals should be routed to a test point
- NCTF these signals are non-critical to function and should not be connected.

Arbitrary connection of these signals to VCC, VDD2, VSS, or to any other signal (including each other) may result in component malfunction or incompatibility with future processors. Refer to the table below.

For reliable operation, always connect unused inputs or bi-directional signals to an appropriate signal level. Unused active high inputs should be connected through a resistor to ground (VSS). Unused outputs may be left unconnected however, this may interfere with some Test Access Port (TAP) functions, complicate debug probing and prevent boundary scan testing. A resistor should be used when tying bi-directional signals to power or ground. When tying any signal to power or ground the resistor can also be used for system testability. Resistor values should be within $\pm 20\%$ of the impedance of the baseboard trace, unless otherwise noted in the appropriate platform design guidelines.

Table 76. GND, RSVD, and NCTF Signals

Processor Internal Pull-Up / Pull- Down on Package 12.13

13.0 Electrical Specifications

Power Delivery 13.1

Notes: 1. FIVR = Fully Integrated Voltage Regulator. For details, refer to Digital Linear Voltage Regulator (DLVR) on page 185.

2. Vcc_{IN AUX} has a few discrete voltages defined by PCH VID.

3. VCC_{1P05} $_{PROC}$, for S processor the power rail is connected to a platform voltage regulator to supply power to the sustaining power rails.

4. Vcc_{MIPILP}: When MIPI DSI interface is been used, this power rail should be connected to 1.24V rail.

5. VCC_{1P05} PROC for P-Processor line power rail is connected to VCC1P05_OUT_FET rail through a power gate at platform, to supply power to the sustain gated power rails.

Power and Ground Pins 13.1.1

All power pins should be connected to their respective processor power planes, while all VSS pins should be connected to the system ground plane. Use of multiple power and ground planes is recommended to reduce I*R drop.

Digital Linear Voltage Regulator (DLVR) 13.1.2

The processor has few internal DLVRs to power gate VccCore, VccGT, and VccSA power rails.

DLVR is internal VR consumes lower power and works within a lower temperature range.

intel

V_{CC} Voltage Identification (VID) **13.1.3**

Intel processors/chipsets are individually calibrated in the factory to operate on a specific voltage/frequency and operating-condition curve specified for that individual processor. In normal operation, the processor autonomously issues voltage control requests according to this calibrated curve using the serial voltage-identifier (SVID) interface. Altering the voltage applied at the processor/chipset causing operation outside of this calibrated curve is considered out-of-specification operation.

The SVID bus consists of three open-drain signals: clock, data, and alert# to both set voltage-levels and gather telemetry data from the voltage regulators. Voltages are controlled per an 8-bit integer value, called a VID, that maps to an analog voltage level. An offset field also exists that allows altering the VID table. Alert can be used to inform the processor that a voltage-change request has been completed or to interrupt the processor with a fault notification.

For VID coding and further information, refer to the IMVP9.1 (FVM feature support version) *PWM Specification* and *Serial VID (SVID) Protocol Specification* .

Fast V-Mode 13.1.4

An SoC integrated detector monitors when the SoC load current exceeds a preset threshold by monitoring for SoC voltage domain voltage droop. The SoC compares the IMVP VR output voltage with a preset threshold voltage (Vtrip) and when the IMVP VR output voltage reached this Vtrip, the SoC throttles itself to reduce the SoC load current.

IMVP9.1 VRs enhance this detector by adding a cycle-by-cycle current limiting feature where the IMVP VR quickly enters cycle by cycle current limit (becomes a current source) with the VR output current limited to a preset value (I TRIP) as set in the VR ICC_limit register

Terminology

- 1. **IccMax** is the maximum current the processor can draw, typically seen running a virus application (stress applications specifically designed to push the SoC to maximum power). This is the current used to design the voltage regulator decoupling.
- 2. **PMax (PL4)** is the maximum instantaneous electrical power drawn by the SoC (per power rail), typically seen running a virus app (stress applications specifically designed to reach maximum consumed power) with an all core turbo and Tjmax scenario.
- 3. **IccMax.app** is less than IccMax and is the electrical current drawn by the SoC (per power rail) while running a typical user realistic application(s) scenario at P0nmax and Tjmax. It corresponds to PMax.App.
- 4. **PMax.App (PL4.App)** is less than PMax and is the power drawn by the SoC (per power rail) while running a typical user realistic application(s) scenario at P0nmax and Tjmax. It corresponds to IccMax.App.
- 5. **ITRIP** is VR output current limit threshold above which the VR goes into current limit. This current is greater than IccMax.App and less than IccMax. It is determined by customer-specific VR current capability and the VR IMON measurement tolerance (TOL IMON).

Generally, **ITRIP** = IccMax.App/(1-TOLI MON). Setting **ITRIP** this way guarantees the VR never goes into current limit below IccMax.APP.

6. **ITRIPMax** is the peak current the VR FETs and inductors could see accounting for the VR controller current measurement tolerance (TOL IMON). The SoC VR and system input power sources must be able to sustain this current for at least 10ms.

NOTE

TOL_IMON can be sometimes called as ITRIP_TOL or ITRIP_ACCURACY

7. **VTRIP** is the output voltage level below which the SoC will self-throttle. In application, this voltage is internally set in the SoC and is not visible external to the SoC. For the purposes of VRTT testing, a Vtrip will be provided for use with the Python* test script used for FVM testing

Benefits

- The SoC droop detector and IMVP cycle by cycle limiting work together to allow the voltage regulator inductors and FETs to be sized for realistic workload current (~ICCMAX.APP) instead of virus currents (ICCMAX)
- Allows power sources to be sized for realistic workload currents, by shielding them from SoC large dynamic loading events that occur when the SoC current exceeds the worst case realistic maximum current (ICCMAX.APP).

Current Excursion Protection (CEP) 13.1.5

This power management is a Processor integrated detector that senses when the Processor load current exceeds a preset threshold by monitoring for a Processor power domain voltage droop at the Processor power domain IMVPVR sense point. The Processor compares the IMVPVR output voltage with a preset threshold voltage (V_{TRIP}) and when the IMVPVR output voltage is equal to or less than V_{TRIP} , the Processor internally throttles itself to reduce the Processor load current and the power

DC Specifications 13.2

The processor DC specifications in this section are defined at the processor signal pins, unless noted otherwise. For pin listing, refer to Package Ballout Mechanical Specification:

- for S/S Refresh/E-Processor line, download the pdf, click \oslash on the navigation pane and refer the spreadsheet, 743844-001 S LGA Ballout.xlsx.
- for HX/HX Refresh-Processor line, download the pdf, click \mathcal{O}_P on the navigation pane and refer the spreadsheet, **743844-001_HX_Ballout.xlsm**.
- for H/H Refresh/P/U/U Refresh-Processor line, download the pdf, click \mathcal{O}_2 on the navigation pane and refer the spreadsheet, **743844-001_HPU_Ballout.xlsm**.
- for PX-Processor line, download the pdf, click \mathcal{O}_ρ on the navigation pane and refer the spreadsheet, **743844-001_PX_Ballout.xlsm**.
- The DC specifications for the DDR4/DDR5/LPDDR4x/LPDDR5/x signals are listed in the *Voltage and Current Specifications* section.
- The *Voltage and Current Specifications* section lists the DC specifications for the processor and are valid only while meeting specifications for junction temperature, clock frequency, and input voltages. Read all notes associated with each parameter.

• ICCMAX is the maximum current processor can draw, typically seen running a virus application (stress applications specifically designed to push the SoC to maximum Power).

With Fast Vmode enabled, output decoupling would see this ICCMax current.

Output decoupling would need to be able to take transient load step up to this ICCMax.

Power Stage (FET/Inductor) would only see ITRIP current

• ICCMax.app is less than IccMax and is the electrical current Drawn by the SoC (per power rail) while running a typical user realistic application(s) scenario at P0nmax and Tjmax.

It Corresponds to Pmax.App, The SoC VR and system input power. Source must be able to sustain this current for at least 10 ms

• AC tolerances for all rails include voltage transients and voltage regulator voltage ripple up to 1 MHz. Refer additional guidance for each rail.

Processor Power Rails DC Specifications 13.2.1

VCCCORE DC Specifications 13.2.1.1

Table 77. Processor VCC_{CORE} Active and Idle Mode DC Voltage and Current **Specifications (S and S-Refresh Processor Line)**

2400 Processor

Table 79. Processor VCCCORE Active and Idle Mode DC Voltage and Current Specifications (U/P/H/PX /U Refresh /H Refresh Processor Lines)

13th Generation Intel® Core™, Intel® Core™ 14th Generation, Intel® Core™ Processor (Series 1) and (Series 2), and Intel® Xeon™ E

Notes: 1. All specifications in this table are based on estimates and simulations or empirical data. These specifications will be updated with characterized data from silicon measurements at a later date.

- 2. Each processor is programmed with a maximum valid voltage identification value (VID) that is set at manufacturing and cannot be altered. Individual maximum VID values are calibrated during manufacturing such that two processors at the same frequency may have different settings within the VID range. Note that this differs from the VID employed by the processor during a power management event (Adaptive Thermal Monitor, Enhanced Intel Speed-step Technology, or low-power states).
- 3. The voltage specification requirements are measured across Vcc_SENSE and Vss_SENSE as near as possible to the processor. The measurement needs to be performed with a 20MHz bandwidth limit on the oscilloscope, 1.5pF maximum probe capacitance, and 1Ω minimum impedance. The maximum length of the ground wire on the probe should be less than 5mm. Ensure external noise from the system is not coupled into the oscilloscope probe.
- 4. Processor VccCORE VR to be designed to electrically support this current.
- 5. Processor VccCORE VR to be designed to thermally support this current indefinitely.
- 6. Long term reliability cannot be assured if tolerance, ripple, and core noise parameters are violated.
- 7. Long term reliability cannot be assured in conditions above or below Maximum/Minimum functional limits.
- 8. PSx refers to the voltage regulator power state as set by the SVID protocol.
- 9. Refer to Intel Platform Design Studio (iPDS) for the minimum, typical, and maximum VCC allowed for a given current and Thermal Design Current (TDC).
- 10.LL measured at sense points.
- 11.Typical column represents IccMAX for commercial application it is NOT a specification it's a characterization of limited samples using limited set of benchmarks that can be exceeded.
- 12.Operating voltage range in steady state.
- 13.LL spec values should not be exceeded. If exceeded, power, performance and reliability penalty are expected.
- 14.Load Line (AC/DC) should be measured by the VRTT tool and programmed accordingly via the BIOS Load Line override setup options. AC/DC Load Line BIOS programming directly affects operating voltages (AC) and power measurements (DC). A superior board design with a shallower AC Load Line can improve on power, performance and thermals compared to boards designed for POR impedance.
- 15.An IMVP9.1 controller to support VccCORE need to have an offset voltage capability and potentially VccCORE output voltage (VID+Offset) may be higher than 1.5V.
- 16.Ripple can be higher if DC TOB is below 20mV, as long as Total TOB is within -35mV/+50mV.
- 17.S Processor Line K/KF/KS i9 SKUs and S Refresh Processor Line K/KF i9 SKUs ICCMAX 400A is an optional Extreme Power Delivery (PD) spec which opportunistically allows better multi-core performance based on customer designs PD and if thermal headroom exists

Table 80. Processor VCCCORE Active and Idle Mode DC Voltage and Current Specifications (E Processor Line)

Notes: 1. All specifications in this table are based on estimates and simulations or empirical data. These specifications will be updated with characterized data from silicon measurements at a later date.

2. Each processor is programmed with a maximum valid voltage identification value (VID) that is set at manufacturing and cannot be altered. Individual maximum VID values are calibrated during manufacturing such that two processors at the same frequency may have different settings within the VID range. Note that this differs from the VID employed by the processor during a power management event (Adaptive Thermal Monitor, Enhanced Intel Speed-step Technology, or low-power states).

3. The voltage specification requirements are measured across Vcc_SENSE and Vss_SENSE as near as possible to the processor. The measurement needs to be performed with a 20MHz bandwidth limit on the oscilloscope, 1.5pF maximum probe capacitance, and 1Ω minimum impedance. The maximum length of the ground wire on the probe should be less than 5mm. Ensure external noise from the system is not coupled into the oscilloscope probe.

- 4. Processor VccCORE VR to be designed to electrically support this current.
- 5. Processor VccCORE VR to be designed to thermally support this current indefinitely.
- 6. Long term reliability cannot be assured if tolerance, ripple, and core noise parameters are violated.
- 7. Long term reliability cannot be assured in conditions above or below Maximum/Minimum functional limits.
- 8. PSx refers to the voltage regulator power state as set by the SVID protocol.
- 9. Refer to Intel Platform Design Studio (iPDS) for the minimum, typical, and maximum VCC allowed for a given current and Thermal Design Current (TDC).
- 10.LL measured at sense points.

11.Typical column represents IccMAX for commercial application it is NOT a specification - it's a characterization of limited samples using limited set of benchmarks that can be exceeded.

- 12.Operating voltage range in steady state.
- 13.LL spec values should not be exceeded. If exceeded, power, performance and reliability penalty are expected.

Table 81. VccIN_AUX Supply DC Voltage and Current Specifications

Notes: 1. All specifications in this table are based on estimates and simulations or empirical data. These specifications will be updated with characterized data from silicon measurements at a later date.

- 2. Long term reliability cannot be assured in conditions above or below Maximum/Minimum functional limits.
- 3. The voltage specification requirements are measured on package pins as near as possible to the processor with an oscilloscope set to 100 MHz bandwidth, 1.5 pF maximum probe capacitance, and 1 MΩ minimum impedance. The maximum length of ground wire on the probe should be less than 5 mm. Ensure external noise from the system is not coupled into the oscilloscope probe.
- 4. LL measured at sense points. LL specification values should not be exceeded. If exceeded, power, performance, and reliability penalty are expected.
- 5. **The LL values are for reference. Must still need to meet the voltage tolerance specification**.
- 6. Voltage Tolerance budget values Include ripples
- 7. Vec_{IN_AUX} is having few point of voltage define by CPU VID

VccGT DC Specifications 13.2.1.2

Table 82. Processor Graphics (VccGT) Supply DC Voltage and Current Specifications

13th Generation Intel® Core™, Intel® Core™ 14th Generation, Intel® Core™ Processor (Series 1) and (Series 2), and Intel® Xeon™ E

2. Each processor is programmed with a maximum valid voltage identification value (VID), which is set at manufacturing and cannot be altered. Individual maximum VID values are calibrated during manufacturing such that two processors at the same frequency may have different settings within the VID range. This differs from the VID employed by the processor during a power or thermal management event (Intel Adaptive Thermal Monitor, Enhanced Intel® SpeedStep Technology, or low-power states).

3. PSx refers to the voltage regulator power state as set by the SVID protocol.

4. Each processor is programmed with a maximum valid voltage identification value (VID), which is set at manufacturing and cannot be altered. Individual maximum VID values are calibrated during manufacturing such that two processors at the same frequency may have different settings within the VID range. This differs from the VID employed by the processor during a power or thermal management event (Intel Adaptive Thermal Monitor, Enhanced Intel® SpeedStep Technology, or low-power states).

- 5. Operating voltage range in steady state.
- 6. Load Line measured at the sense point.
- 7. An IMVP9.1 controller to support VCCGT need to have an offset voltage capability and potentially VCCGT output voltage (VID+Offset) may be higher than 1.5V
- 8. Ripple can be higher if DC TOB is below 20mV, as long as Total TOB is within -35mV/+50mV.

V_{DD2} DC Specifications **13.2.1.3**

Table 83. Memory Controller (VDD2) Supply DC Voltage and Current Specifications

Notes: 1. All specifications in this table are based on estimates and simulations or empirical data. These specifications will be updated with characterized data from silicon measurements at a later date.

2. The current supplied to the DIMM modules is not included in this specification.

3. Includes AC and DC error, where the AC noise is bandwidth limited to under 1 MHz, measured on package pins.

4. No requirement on the breakdown of AC versus DC noise.

5. The voltage specification requirements are measured on package pins as near as possible to the processor with an oscilloscope set to 100 MHz bandwidth, 1.5 pF maximum probe capacitance, and 1 MΩ minimum impedance. The maximum length of ground wire on the probe should be less than 5 mm. Ensure external noise from the system is not coupled into the oscilloscope probe.

6. For Entry Server applications (Windows and Linux Server OS) the expected worst-case peak current draw for the VDD2 rail will be 4.5A, this is for conditions with Tj under 95°C.

Vcc1P05_PROC DC Specifications 13.2.1.4

Table 84. Vcc1P05_PROC Supply DC Voltage and Current Specifications

Notes: 1. All specifications in this table are based on estimates and simulations or empirical data. These specifications will be updated with characterized data from silicon measurements at a later date.

2. Long term reliability cannot be assured in conditions above or below Maximum/Minimum functional limits.

3. The voltage specification requirements are measured on package pins as near as possible to the processor with an oscilloscope set to 100 MHz bandwidth, 1.5 pF maximum probe capacitance, and 1 MΩ minimum impedance. The maximum length of ground wire on the probe should be less than 5 mm. Ensure external noise from the system is not coupled into the oscilloscope probe.

4. Vcc_{1P05_PROC} may be named in other document as Vcc_{1P05_CPU}

5. Vcc1P05_PROC momentarily **may rise** to 1.15V during certain scenarios. **No side effects are expected**.

Vcc1P8_PROC DC Specifications 13.2.1.5

Table 85. Vcc1P8_PROC Supply DC Voltage and Current Specifications

Notes: 1. All specifications in this table are based on estimates and simulations or empirical data. These specifications will be updated with characterized data from silicon measurements at a later date.

2. Long term reliability cannot be assured in conditions above or below Maximum/Minimum functional limits.

3. The voltage specification requirements are measured on capacitors pads near to the package, with an oscilloscope set to 100 MHz bandwidth, 1.5 pF maximum probe capacitance, and 1 MΩ minimum impedance. The maximum length of ground wire on the probe should be less than 5 mm. Ensure external noise from the system is not coupled into the oscilloscope probe.

4. Vcc_{1P8} _{PROC} power rail may be named in different document as Vcc_{1P8} $_{\text{CPU}}$

5. For S-process line, AC noise spec include VR self generated noise or input source AC noise that passes through to VR output and droop/overshoot due to transient load.

Processor Interfaces DC Specifications 13.2.2

DDR4 DC Specifications 13.2.2.1

Table 86. DDR4 Signal Group DC Specifications

Notes: 1. All specifications in this table apply to all processor frequencies. Timing specifications only depend on the operating frequency of the memory channel and not the maximum rated frequency

2. V_{IL} is defined as the maximum voltage level at a receiving agent that will be interpreted as a logical low value.

- 3. V_{IH} is defined as the minimum voltage level at a receiving agent that will be interpreted as a logical high value.
- 4. V_{IH} and V_{OH} may experience excursions above V_{DD2}. However, input signal drivers should comply with the signal quality specifications.
- 5. Pull up/down resistance after compensation (assuming ±5% COMP inaccuracy). Note that BIOS power training may change these values significantly based on margin/power trade-off. Refer to processor I/O Buffer Models for I/V characteristics.
- 6. ODT values after COMP (assuming ±5% inaccuracy). BIOS MRC can reduce ODT strength towards
- 7. The minimum and maximum values for these signals are programmable by BIOS to one of the two sets.
- 8. SM_RCOMP[x] resistance should be provided on the system board with 1% resistors. SM_RCOMP[x] resistors are to VSS. Values are pre-silicon estimations and are subject to change.
- 9. SM_DRAMPWROK must have a maximum of 15 ns rise or fall time over VDD2 * 0.30 ±100 mV and the edge must be monotonic.
- 10.SM_VREF is defined as $V_{DD2}/2$ for DDR4
- $11.R_{ON}$ tolerance is preliminary and might be subject to change.
- 12.Maximum-minimum range is correct but center point is subject to change during MRC boot training.
- 13. Processor may be damaged if V_{IH} exceeds the maximum voltage for extended periods.
- 14.AC peak noise of VREFCA will not be deviate by more than +/-1% of VDD (for reference +/-12mV).
- 15.+/-100mV if for frequency above 2400, 2400 and below the spec is +/-60mV.

DDR5 DC Specifications 13.2.2.2

Table 87. DDR5 Signal Group DC Specifications

13th Generation Intel® Core™, Intel® Core™ 14th Generation, Intel® Core™ Processor (Series 1) and (Series 2), and Intel® Xeon™ E

Notes: 1. All specifications in this table apply to all processor frequencies.Timing specifications only depend on the operating frequency of the memory channel and not the maximum rated frequency

- 2. V_{IL} is defined as the maximum voltage level at a receiving agent that will be interpreted as a logical low value.
- 3. V_{IH} is defined as the minimum voltage level at a receiving agent that will be interpreted as a logical high value.
- 4. V_{IH} and V_{OH} may experience excursions above V_{DD2} . However, input signal drivers should comply with the signal quality specifications.
- 5. Pull up/down resistance after compensation (assuming ±5% COMP inaccuracy). Note that BIOS power training may change these values significantly based on margin/power trade-off. Refer to processor I/O Buffer Models for I/V characteristics.
- 6. ODT values after COMP (assuming ±5% inaccuracy). BIOS MRC can reduce ODT strength towards
- 7. The minimum and maximum values for these signals are programmable by BIOS to one of the two sets.

8. SM_RCOMP[x] resistance should be provided on the system board with 1% resistors. SM_RCOMP[x] resistors are to VSS. Values are pre-silicon estimations and are subject to change.

- 9. SM_DRAMPWROK must have a maximum of 15 ns rise or fall time over VDD2 $*$ 0.30 \pm 100 mV and the edge must be monotonic.
- 10.SM_VREF is defined as $V_{DD2}/2$ for DDR5
- 11.RON tolerance is preliminary and might be subject to change.
- 12.Maximum-minimum range is correct but center point is subject to change during MRC boot training.
- 13. Processor may be damaged if V_{IH} exceeds the maximum voltage for extended periods.

LPDDR4x DC Specification 13.2.2.3

Table 88. LPDDR4x Signal Group DC Specifications

Notes: 1. Unless otherwise noted, all specifications in this table apply to all processor frequencies. Timing specifications only depend on the operating frequency of the memory channel and not the maximum rated frequency

2. V_{IL} is defined as the maximum voltage level at a receiving agent that will be interpreted as a logical low value.

3. V_{IH} is defined as the minimum voltage level at a receiving agent that will be interpreted as a logical high value. 4. V_{IH} and V_{OH} may experience excursions above V_{DD2} . However, input signal drivers should comply with the signal quality specifications.

5. Pull up/down resistance after compensation (assuming ±5% COMP inaccuracy). Note that BIOS power training may change these values significantly based on margin/power trade-off. Refer to processor I/O Buffer Models for I/V characteristics.

8. SM_RCOMP[x] resistance should be provided on the system board with 1% resistors. SM_RCOMP[x] resistors are to VSS. Values are pre-silicon estimations and are subject to change.

9. SM_DRAMPWROK must have a maximum of 15 ns rise or fall time over VDD2 $*$ 0.30 \pm 100 mV and the edge must be monotonic.

 $10.R_{ON}$ tolerance is preliminary and might be subject to change.

11.Maximum-minimum range is correct but center point is subject to change during MRC boot training.

12. Processor may be damaged if V_{IH} exceeds the maximum voltage for extended periods.

PCIe* DC and Timing Specifications 13.2.2.5

The PCIe Controller and Transmit/Receive Physical Layer PHYs are compliant with the "PCI Express* Base Specification Revision 5.0". For PCIe electrical specifications, refer to the PCI Express Base Specification Revision 5.0, which is available at [https://](https://pcisig.com/) [pcisig.com/.](https://pcisig.com/)

PCI Express* Graphics (PEG) Group DC Specifications 13.2.2.6

Table 90. PCI Express* Graphics (PEG) Group DC Specifications

Notes: 1. Refer to [PCIe* Interface](#page-138-0) on page 139 for more details.

2. Low impedance defined during signaling. Parameter is captured for 5.0 GHz by RLTX-DIFF.

3. PEG_RCOMP resistance should be provided on the system board with 1% resistors. COMP resistors are to VCCIO_OUT. PEG_RCOMP- Intel allows using 24.9 Ω 1% resistors.

4. DC impedance limits are needed to ensure Receiver detect.

5. The Rx DC Common Mode Impedance should be present when the Receiver terminations are first enabled to ensure that the Receiver Detect occurs properly. Compensation of this impedance can start immediately and the 15 Rx Common Mode Impedance (constrained by RLRX-CM to 50 Ω ±20%) should be within the specified range by the time Detect is entered.

Digital Display Interface (DDI) DC Specifications 13.2.2.7

Table 91. DSI HS Transmitter DC Specifications

2. A transmitter should minimize ΔV_{OD} and $\Delta V_{CMTX(1,0)}$ in order to minimize radiation, and optimize signal integrity

Table 92. DSI LP Transmitter DC Specifications

13th Generation Intel® Core™, Intel® Core™ 14th Generation, Intel® Core™ Processor (Series 1) and (Series 2), and Intel® Xeon™ E 2400 Processor

Notes: 1. Applicable when the supported data rate <= 1.5 Gbps.

- 2. Applicable when the supported data rate > 1.5 Gbps.
	- 3. Though no maximum value for ZOLP is specified, the LP transmitter output impedance shall ensure the TRLP/TFLP specification is met.
	- 4. The voltage overshoot and undershoot beyond the VPIN is only allowed during a single 20 ns window after any LP-0 to LP-1 transition or vice versa. For all other situations it must stay within the VPIN range.
- 5. This value includes ground shift.

2. DC specification for: PROC_AUDOUT, PROC_AUDIN, PROC_AUDCLK.

CMOS DC Specifications 13.2.2.8

Table 94. CMOS Signal Group DC Specifications

Notes: 1. All specifications in this table apply to all processor frequencies.

2. The Vcc referred to in these specifications refers to instantaneous $Vec_{1p05_PROC/IO}$.

3. For V_{IN} between "0" V and Vcc_{1p05_PROC}. Measured when the driver is tri-stated.

4. VIH may experience excursions above Vcc_{1p05_PROC}. However, input signal drivers should comply with the signal quality specifications.

5. Refer to the processor *I/O Buffer Models* for I/V characteristics.

GTL and OD DC Specification 13.2.2.9

Table 95. GTL Signal Group and Open Drain Signal Group DC Specifications

Notes: 1. All specifications in this table apply to all processor frequencies.

2. The Vcc referred to in these specifications refers to instantaneous Vcc1p05_PROC/IO.

3. For V_{IN} between 0 V and Vcc. Measured when the driver is tri-stated.

4. V_{IH} and V_{OH} may experience excursions above Vcc. However, input signal drivers should comply with the signal quality specifications.

5. Refer to the processor *I/O Buffer Models* for I/V characteristics.

PECI DC Characteristics 13.2.2.10

The PECI interface operates at a nominal voltage set by Vec_{1p05_PROC} . The set of DC electrical specifications shown in the following table is used with devices normally operating from a $Vec_{1P05-PROC}$ interface supply.

Vcc_{1p05} _{PROC} nominal levels will vary between processor families. All PECI devices will operate at the Vcc_{1p05} $_{PROC}$ level determined by the processor installed in the system.

Table 96. PECI DC Electrical Limits

3. The PECI buffer internal pull up resistance measured at $0.75*$ Vcc_{1p05_PROC}.

Input Device Hysteresis

The input buffers in both client and host models should use a Schmitt-triggered input design for improved noise immunity. Use the following figure as a guide for input buffer design.

Figure 27. Input Device Hysteresis

14.0 Package Mechanical Specifications

Package Mechanical Attributes 14.1

The S/S refresh Processor Lines use a Flip Chip technology available in a Land Grid Array (LGA) package. The following table provides an overview of the package mechanical attributes. For specific dimensions (die size, die location, and so on), refer to the processor package mechanical drawings.

15.0 CPU And Device IDs

CPUID 15.1

Table 101. CPUID Format

NOTES

- The Extended Family, Bits [27:20] are used in conjunction with the Family Code, specified in Bits[11:8], to indicate whether the processor belongs to Intel® Core[™] processor family.
- The Extended Model, Bits [19:16] in conjunction with the Model Number, specified in Bits [7:4], are used to identify the model of the processor within the processor's family.
- The Family Code corresponds to Bits [11:8] of the EDX register after RESET, Bits [11:8] of the EAX register after the CPUID instruction is executed with a 1 in the EAX register, and the generation field of the Device ID register accessible through Boundary Scan.
- The Model Number corresponds to Bits [7:4] of the EDX register after RESET, Bits [7:4] of the EAX register after the CPUID instruction is executed with a 1 in the EAX register, and the model field of the Device ID register accessible through Boundary Scan.
- The Stepping ID in Bits [3:0] indicates the revision number of that model.
- When EAX is initialized to a value of '1', the CPUID instruction returns the Extended Family, Extended Model, Processor Type, Family Code, Model Number and Stepping ID value in the EAX register. Note that the EDX processor signature value after reset is equivalent to the processor signature output value in the EAX register.

Cache and TLB descriptor parameters are provided in the EAX, EBX, ECX and EDX registers after the CPUID instruction is executed with a 2 in the EAX register.

PCI Configuration Header 15.2

Every PCI-compatible function has a standard PCI configuration header, as shown in the table below. This includes mandatory registers (Bold) to determine which driver to load for the device. Some of these registers define ID values for the PCI function, which are described in this chapter.

Table 102. PCI Configuration Header

Byte3	Byte2	Byte1	Byte0	Address
Device ID		Vendor ID (0x8086)		00h
Status		Command		04h
Class Code			Revision ID	08h
BIST	Header Type	Latency Timer	Cache Line Size	0Ch
Base Address Register0 (BAR0)				10 _h
Base Address Register1 (BAR1)				14h
Base Address Register2 (BAR2)				18h
Base Address Register3 (BAR3)				1Ch
Base Address Register4 (BAR4)				20h
Base Address Register5 (BAR5)				24h
